Context

Assessment of surgical performance in the field of congenital heart surgery is very difficult, so many risk scoring systems have been developed. The most popular used systems nowadays are the risk adjustment for congenital heart surgery (RACHS-1) system, Aristotle basic complexity score (ABC score), and the Society of Thoracic Surgeons-European Association for Cardiothoracic Surgery (STS-EACTS) mortality score and categories.

Aims

The aims of the study were the application of the three popular risk scoring systems to Assiut University Hospital for evaluation of the outcome results, determination of the correlations between the mortality and morbidity to the risk categories of these systems, comparison with other cardiac centers worldwide, and managing the factors that lead to different outcome in an attempt to improve our performance.

Materials and methods

A retrospective descriptive study including all pediatric patients (ages ranging from 0 to 16 years old, excluding preterm babies) who underwent cardiac surgery in Assiut University Hospital between January 2008 and December 2017 was conducted.

Statistical analysis

The receiver operating characteristic curve and univariate and multivariate analyses were performed with SPSS 16.0 for Windows.

Results

Postoperative in-hospital mortality was 5.8%, with increasing mortality rates at the higher levels of the RACHS-1 and the ABC. The mean ABC score was 5.57 ± 2.07 , which represents a complexity between ABC levels 1 and 2. The mean STS-EACTS mortality score was 0.375 ± 0.376 , which placed our complexity of procedures into categories 1–2.

Conclusion

The RACHS-1, ABC, and STS-EACTS mortality scoring systems are useful tools for assessing mortality discharge in a medium volume cardiac center in Egypt. These scores imply a procedural-based level of complexity in the institute, which would be useful information for a longitudinal study.

Introduction

Surgical performance assessment in congenital heart surgery should not depend on the hospital mortality only but the complexity of the operation must be regarded; risk stratification systems have been developed to measure the performance in congenital heart surgery field [1].

Risk adjustment for congenital heart surgery (RACHS-1) method was introduced in 2002, and it stratified the patients into 6 categories depending on the age at the time of operation and the type of operation [2].

Aristotle basic complexity score (ABC score) developed in 2004 categorized the operations according to scores (range: 1.5–15) and levels 1–4 [3]. The European Association for Cardiothoracic Surgery (EACTS) and the Society of Thoracic Surgeons (STS) introduced a new model for risk stratification (STS-EACTS mortality scores and categories) in 2009 and applied it on their databases in 2009 [4].

We applied the three classification tools to the Assiut University Hospital patients to test our results in comparison with other centers. Besides the direct outcome comparison, we looked for correlations

between the risk category and both the mortality and morbidity and also the risk factors for different outcomes in our center.

Materials and methods

Data source

The present study was designed as a retrospective descriptive study and approved by the Assiut Faculty of medicine Review Board and Ethics Committee (No. 17100404). All pediatric patients (ages ranging from 0 to 16 years old, excluding preterm babies) who underwent cardiac surgery in Assiut University Hospital between January 2008 and December 2017 were identified using the Assiut University Hospital database. Demographic data was reviewed for age at the first presentation at the hospital, sex, age at the onset of symptom presentation, presence of genetic syndrome, and diagnosis of congenital heart disease. The preoperative and intraoperative data included type of operation, cardiopulmonary bypass time (CPB time), and aortic cross clamp time (AoX time). The postoperative data included outcomes like in-hospital morbidities and mortalities, which were categorized by the RACHS-1 method, ABC level, and STS-EACTS mortality categories [2-4]. Retrospective variables were identified, and a statistical analysis was performed on the effects of preoperative and intraoperative factors on surgical outcomes.

Study variables

Postoperative death before hospital discharge was used as the main outcome variable. For secondary outcome variables, postoperative morbidities were considered. These included cardiac arrest, reoperation, postoperative reintubation, low cardiac output, acute renal failure requiring peritoneal dialysis, pyrexia (>38°C), pleural effusion, and serious cardiac arrhythmia such as complete Atrio-Ventricular (AV) block, junctional ectopic tachycardia, supraventricular tachycardia, atrial ectopic tachycardia, ventricular tachycardia, and ventricular fibrillation requiring medical or electrical cardioversion.

Data analysis

Patients' baseline characteristics and potential confounders were summarized using descriptive statistics (showing the percentage, median, and range). The receiver operating characteristic (ROC) curve was examined for validation of the RACHS-1 level, ABC level, and STS-EACTS mortality categories. Associations between potential risk factors and poor outcomes were assessed with univariate analysis. Continuous variables were assessed with a Mann–Whitney *U*-test, and the categorical variables were evaluated by a Fisher's exact test or a χ^2 -test. Multivariate analysis was performed with forward stepwise logistic regression, combined for each outcome. A *P* value less than 0.05 was considered to be statistically significant. Statistical analysis was performed with SPSS 16.0 for Windows (SPSS Inc., Chicago, Illinois, USA).

Results

Demographic data

During the 10-year study period, a total of 1095 congenital cardiac surgical procedures were performed on patients at Assiut University Hospital. Their ages were less than 16 years old, and the study excluded preterm babies. Demographic data of these patients are shown in Table 1. The mean weight of our patients is shown in Fig. 1.

Weight at time of surgery	17.1±11.5 (3-87)
<15 kg	593 (54.15) (9.72±2.661)
>15 kg	502 (45.84) (25.92±11.823)

Surgical procedures

During the 10 years of the study period, a total of 1095 pediatric cardiac surgical procedures were performed. The majority of the procedures were open-heart surgery (77.5%; n = 849). The most frequent open-heart procedures were tetralogy of Fallout repair, ventricular septal defect closure, and atrial septal defect closure (19.54, 17.9, and 17.17%, respectively) (see Table 2).

Average cardiopulmonary bypass time and average a ortic cross clamp time were 76.05 ± 40.45 and 49.3 ± 29.9 min, respectively.

Mostoftheprocedures were stratified into the RACHS-1 levels [2] of 1 and 2 (38.9 and 51%, respectively), ABC levels [3] of 1 and 2 (39.3 and 36.3%, respectively), and STS-EACTS mortality categories [4] of 1 and 2 (66.2 and 24.2%, respectively) (see Table 3 and Figs. 2–4).

Mortality

Overall in-hospital postoperative mortality in the present study was 5.83% (64 of 1095); see Fig. 5 and Table 4 for causes of mortality.

Figure 2

Year-to-year changes in the distribution of cases along the risk adjustment for congenital heart surgery-1 risk categories.

Year-to-year changes in the distribution of cases along the Society of Thoracic Surgeons-European Association for Cardiothoracic Surgery categories.

Using Pearson's correlation test, we found that younger age, smaller weight, higher RACHS-1 levels, higher ABC levels, higher STS-EACTS mortality categories, longer bypass time, and longer cross clamp time were significantly associated with increased mortality. The bypass times and aortic cross clamp time significantly affected the mortality, as they generally reflect the difficulty of procedures and the complexity of diseases as seen in Table 5.

The calculated surgical performance [3] of the department is as follows = hospital survival (1031/1095 = 94.15%)×the mean ABC score (5.55)/100 = 5.198. Fig. 6 shows changes in our performance year to year.

Using the ROC curve statistical method, we tested our mortality results against the 3 risk scoring systems to measure the sensitivity and specificity of these risk scores, and hence detect the method with the best predictability for the mortality in our cases. The area under the ROC curve was measured for each risk scoring system. Larger values of the test result

ABC, Aristotle basic complexity; RACHS-1, risk adjustment for congenital heart surgery; STS-EACTS, Society of Thoracic Surgeons-European Association for Cardiothoracic Surgery.

variable(s) indicate stronger evidence for a positive actual state (better matching). ABC complexity levels system provided the best results with area under the curve of 0.734, followed by the RACHS-1 risk categories system with area under the curve of 0.710, and the least predictability was by STS-EACTS mortality categories system with an area under the curve of 0.574 (Fig. 7 and Table 6).

Morbidity

Multivariate analysis identified cardiopulmonary bypass time, cross clamp time, RACHS-1 category, ABC levels, and STS-EACTS mortality categories as risk factors for prolonged postoperative hospital stay (P < 0.05), as shown in Table 7. The most common events were cardiac arrhythmia events, which required medical intervention; temporary pacing or electrical cardioversion (29.4%); and postoperative pyrexia and chest infections (9.1%), as seen in Table 8.

Discussion

In the present study, 1095 operations have been done in our department from January 2008 to December 2017, with changes in the number of procedures from year to year. The mean age of our cases is 5.05 years and

Receiver operating characteristic curves for the different risk stratification systems.

the mean weight is 17.1 kg, and approximately 54.15% of the cases have a weight less than 15 kg.

Most procedures were open-heart surgery (77.5%; n = 849). The most frequent open-heart procedures were tetralogy of Fallout repair, ventricular septal defect closure, and atrial septal defect closure (19.54, 17.9, and 17.17%, respectively).

Most of the procedures were stratified into the RACHS-1 levels of 1 and 2 (38.9 and 51%, respectively), ABC levels of 1 and 2 (39.3 and 36.3%, respectively), and STS-EACTS mortality categories of 1 and 2 (66.2 and 24.2%, respectively).

Before studying our results regarding mortality, we have to highlight two important points whose influence on our hospital mortality is not negligible:

- (1) First point center in establishment phase: considering the initial establishment of a center, even with experience in the surgical treatment of congenital heart disease, the patient outcomes are extremely dependent of the infrastructure at preoperative, transoperative and postoperative times, with special emphasis on the many difficulties faced in the establishment process of a surgical center of high complexity in our country. We found that mortality rates also reflect the many difficulties encountered, even in cases of low complexity, with 5.09 and 4.1% in STS-EACTS category 1 and 2, respectively, which is considered high in comparison with a study on STS and EACTS database that was found to be 0.55% for category 1 and 1.7% for category 2 [4].
- (2) Second point low total volume: despite having a cardiovascular surgery center and a medical residency program, the annual average of surgery cases in congenital heart disease in patients younger than 16 years is fewer than 110 surgeries/year. The surgical volume is a factor whose association with hospital mortality is well established in the literature [5].

Renal failure required peritoneal dialysis	4 (0.37)
Total	636 (58.1)

ICT, Inter-costal tube.

We bring to attention the recent retrospective study of Vinocur *et al.* [5] enrolling 49 American centers, which was included in the Pediatric Cardiac Care Consortium database. After analysis of 85 023 surgeries (45.5% of which were categories 1 and 2 by RACHS-1 method), the mortality rate was 6.2% [5].

In our center in Assiut University Hospital, most of the procedures were stratified into the RACHS-1 levels of 1 and 2 (38.9 and 51%, respectively), and the mortality rate is 5.8%.

It is important to underline the findings of the study of Welke *et al.* [6], and the fact that the inverse correlation between volume and mortality has been demonstrated for the group with more complex procedures (Aristotle score >3). Centers with a volume less than 150 surgeries/year had higher mortality rates in comparison with centers with volume greater than or equal to 350 surgeries [6].

Our view agrees with what was described in the study by Welke *et al.* [6], in which there might be intrinsic factors associated with the centers, other than surgical volume itself, influencing the outcomes. It is necessary to identify these factors with appropriate studies in parallel to the employment of measures aiming to augment the surgical volume. It is precisely this increase of the volume that theoretically reduces the influence of these factors, promoting the interaction of staff and the establishment of a necessary routine in all steps involved (preoperative, transoperative, and postoperative).

Postoperative in-hospital all-over mortality discharge was 5.8%, with increasing mortality rates at the higher levels of the RACHS-1 and the ABC. Nevertheless, no patients were at RACHS-1 levels 5 and 6. The mean ABC score was 5.55 ± 2.01 , which represents a complexity between ABC levels 1 and 2. Likewise, the mean STS-EACTS mortality score was 0.374 ± 0.376 , which again placed our complexity of procedures into categories 1–2. These scores imply a procedural-based level of complexity in the institute, which would be useful information for a longitudinal study.

Regarding the variability of in-hospital mortality discharge from year to year with the highest rate in 2010 (16/155 = 10.3%) and in 2016 (11/96 = 11.45) the reason for that was transition of our pediatric cardiac surgery unit from place to place, lack of resources and equipment, and our trial to operate on cases with higher complexity, which has also affected on our performance in these years (2010 = 4.9 and 2016 = 5.2), otherwise our performance was steady in the other years.

Overall, the present study besides a previous study applied on Assiut University Hospital conducted by Ghoneim *et al.* [7] shows that the three scoring systems can be applied to a medium volume hospital. The areas under the ROC curves for the ABC and RACHS-1, for predicting in-hospital mortality, are impressive, with 0.734 and 0.710, respectively.

The mortality rate distributed by the ABC risk categories looks a bit different from those of the RACHS-1 or STS-EACTS systems. In the ABC complexity categories, the highest mortality percentage was found at level 3 (50%), followed by level 2 (37.5%), then level 1 (6.25%) and level 4 (6.25%), whereas in the RACHS-1, the highest mortality percentage was found at category 2 (68.75%), followed by category 3 (23.4%).

Using Pearson's correlation test, we found that younger age, smaller weight, higher RACHS-1 levels, higher ABC levels, higher STS-EACTS mortality categories, longer bypass time, and longer cross clamp time were significantly associated with increased mortality. The bypass times and aortic cross clamp time significantly affect the mortality as they generally reflect the difficulty of procedures and the complexity of diseases.

Regarding the causes of mortality postoperatively, it was found that the most common cause was low cardiac output (45.3%) followed by uncontrolled arrhythmia (12.5%), both of which failed to be managed properly in ICU. That reveals the importance of increasing our experience in the management of such cases in the postoperative ICU. Moreover, limited availability of some drugs such as milrinone (phosphodiesterase inhibitor, a potent ino-dilator) and dual chamber pacing devices pay important role in those deaths.

Using the ROC curve statistical method, we tested our mortality results against the 3 risk scoring systems to measure the sensitivity and specificity of these risk scores, and hence detect the method with the best predictability for the mortality in our cases. The area under the ROC curve was measured for each risk scoring system. Larger values of the test result variable (s) indicate stronger evidence for a positive actual state (better matching). ABC complexity levels system provided the best results with area under the curve of 0.734, followed by the RACHS-1 risk categories system with area under the curve of 0.710, and the least predictability was by STS-EACTS mortality categories system with an area under the curve of 0.574.

The most common complications were postoperative serious arrhythmias (22.4%), followed by postoperative fever and chest infections (9.1%). In comparison with others, Chodchanok *et al.* [8] in their series from Thailand, reported postoperative fever (43%), and bleeding tamponade, causing unstable hemodynamics requiring reoperation (9.6%) to be their most common postoperative complications. Other morbidities appeared to be similar to those reported by other authors [8–10].

Comparison of our results with the results of other centers in developing countries was found satisfactory regarding the overall mortality discharge (5.8%), which was found to be less than leading centers in other developing countries, for example, Messejana Hospital,Fortaleza,Brazil2003–2014(11.5%)[11] and Sri Jayadeva Institute, India 2007–2013 (7.91%) [12].

Regarding the mortality in relation to risk scores especially of low complexity (RACHS catagory 1 = 0.7% and RACHS catagory 2 = 7.78%), it was in the same range.

By comparing our results to those of the largest database from the STS and EACTS congenital registry [4], the performance at our center has a higher mortality, especially for higher STS-EACTS categories. Jacobs and colleagues in his 2009 study of 58 506 operations at 73 centers revealed an overall discharge mortality as follows: in category 1 = 0.55% (0–1.0%), category 2 = 1.7% (1.0–2.2%), category 3 = 2.6% (1.1–4.4%), category 4 = 8.0% (6.3–11.1%), and category 5 = 18.4% (13.9–27.9%) [4]. Our series revealed mortality rates of 5.09, 4.1, 23.8,

STS-EACTS, Society of Thoracic Surgeons-European Association for Cardiothoracic Surgery.

and 13.09% for categories 1–4, respectively, with no operations in category 5. Accordingly, the performance of congenital heart surgery at our center needs to be improved to achieve a standard of quality matching the STS-EACTS results.

Tables 9–11 show the comparison of our results with the results of other centers of the world from both developed and developing countries.
