Abstract

A well-balanced diet requires essential vitamins, minerals, high protein, and essential amino acids, such as those found in camel meat. A total of 50 camel carcasses, weighing 25 kg, were obtained, with 500g samples collected from various retail markets in Jeddah city. Bacterial isolations, including *Escherichia coli, Staphylococcus aureus, Salmonella sp, Klebsiella pneumoniae, Pseudomonas aeruginosa, and Hafnia alvei*, were carried out using bacteriological plating, microscopic inspection, and serological testing. The camel samples' bacterial profiles revealed the presence of *Staphylococcus* spp. in approximately 70% and 40% of the analyzed samples, respectively. Positive aerobic bacteria constituted 50% of the entire camel samples. Only 2 out of 50 camel samples (5%) tested positive for *Pseudomonas spp.* All camel meat samples met the microbiological criteria for food (GSO 1016/2015) and were deemed safe for human consumption. This research offers promising solutions to combat *E. coli, Staphylococcus aureus, Staphylococcus saprophyticus, Pseudomonas aeruginosa, Klebsiella pneumoniae, and Hafnia alvei* contamination in meat products.

Keywords: *Staphylococcus aureus, Staphylococcus saprophyticus, Pseudomonas aeruginosa, Klebsiella pneumoniae, Hafnia alvei,* PCR detection.

1. Introduction

Meat is one of the most favorable food items for people around the world due to it delicious taste and aroma with variety of dishes and products which prepared by meat, in addition to its richness of essential proteins, minerals and vitamins [1]. Generally speaking, beef, poultry, chevon, and camel meat are some of the many varieties of meat that are frequently consumed in Islamic countries. Due to its high-quality protein and less fat, lower calories, and lower cholesterol levels than other animal meats, camel meat is one of the healthiest meat kinds from the standpoint of health and nutritional value [2].

Camel flesh contains between 20 and 23% protein, which considered as one of the excellent sources of protein in diet[3]. On the other side fat content in Camel meat about (1.51%) with lower cholesterol level (57.56 mg/100 g) which scored significantly lower results when comparing withbeef (6.83%) and mutton (4.56%) fat and (74.5 mg/100 g) beef cholesterol[4-6]**.**

As a result, camel meat can become a popular type of meat all over the world despite the fact that eating meat has a detrimental impact on human health due to the large level of saturated fat content. Furthermore, camel meat consumption has additional benefits due to the high amount of polyunsaturated fatty acids and low cholesterol [7].

According to **Ulmer *et al.*** [8] camel shoulder muscles contain the following amounts of minerals and vitamins per 100 g: calcium 6.5 g, magnesium 23.6 g, potassium 293 g, sodium 58.2 g, zinc 3.4 g, iron 2.1 g, copper 0.2 g, thiamine 0.12 g, riboflavin 0.18 g, pyridoxine 0.25 g, and alpha-tocopherol 0.61 g. The researchers discovered that camel meat has a high iron level (45.5 mg/100 g), compared to beef (1.8 mg/100 g), mutton (4.05 mg/100 g), and chicken (0.4 mg/100 g). Vitamin C, B3, B6, B12, D, and E are far more abundant in camel meat than in beef, mutton, and fowl [6].

There are many different types of foodborne diseases, and they continue to seriously harm people's health everywhere in the world. Many different microorganisms that are transmitted through food are the cause of human diseases. Microbes are present. (*Escherichia coli*(*E. coli*), *Staphylococcus aureus* and *Staphylococcus saprophyticus*) in food poses food poisoning problem [9].Foodborne infections caused by consuming

contaminated food are becoming more common around the world. *E. coli*, *Staphylococcusaureus*, *Staphylococcussaprophyticus*, *Klebsiellapneumoniae*, *Pseudomonas aeruginosa,* and *Hafnia alvei* are examples of foodborne illnesses [10]. Food poisoning is a general word that refers to a number of unpleasant conditions. It is also sometimes referred to as foodborne illness or illness brought on by eating contaminated food. The majority of physical signs of food poisoning include nausea, vomiting, watery diarrhea (sometimes bloody), stomach cramps, fever, and other symptoms.These illnesses often last a few hours to several days and might manifest as mild to severe instances [11-13].

Additionally, microbial growth can develop inside of a person's body (food infection), generate toxins (food intoxication), or grow inside of a person's body (food poisoning) and release toxins (food toxico-infection) [14].
The purpose of meat hygiene practices is to avoid the spread of disease to humans and to provide them with safe whole-animal meat for eating, especially now that meat is regarded as a necessary food and a type of high-quality animal protein [15].
Although Arabian Consuming Camel meat more than other nations but there is shortage in studies which concern with microbial evaluation of Camel meat therefore this study aimed to Microbial evaluation and molecular identification of microorganisms isolated from camel meat sold in Jeddah markets.

2. Experimental

2.1. Collection and Preparation of Samples (Figure 1)

Fifty camel carcasses totaling 25 kg of camel samples were obtained; 500g of each sample was acquired from a different retail market in Jeddah city. Sterile technique was carefully observed during sample collection. Samples were gathered and sent right away to the microbiology postgraduate lab at the University of Jeddah's College of Science in pre-chilled, insulated containers with frozen packs. As demonstrated in the table below, all samples were made in accordance with the method advised by **APHA** [16]. Each sample was combined with 9 ml of sterile buffered peptone water 0.1% under aseptic conditions, and the mixture was then homogenized to create a dilution (1/10).

2.2. Isolation of Aerobic and Anaerobic Colony Count

Spread the inoculum over the surface of the agar using a glass spreader using the spread plate method to determine the aerobic colony count, the plates should be incubated for 48 h at 37°C in an anaerobic jar (Gaspak + anaerobic system) after solidification for anaerobic counts. count the colonies on dishes containing 30–300 colonies and record the results every dilution counted. The 10-fold reduced inoculation volume should be taken into consideration by multiplying final values by 10 (ten). CFU/g is used to express results.Isolation of total *E. coli* usingEosin methylene blue agarafter 30 - 35 °C for 24 h.incubation the colonies appeared as a green metallic luster which counted. While the intestinal air colonies are pink/orange in color with darker centers. Isolated typical colonies or colonies most likely to be *E. coli* were subjected to further identification by microscopic examination and biochemical tests including Indole (+), methyl red (+), Voges-Proskauer (-) and Citrate (-) [17].

K. pneumoniae colonies on Eosin-methylene blue (EMB) agar medium(Techno Pharmchem, Vardhman City Center, New Delhi, India)varies from pink to purple, grew, when incubated at 37°C/24 h, then isolate colony was found using Gram's staining, colony characteristics, and biochemical assays. Indole negative (-ve), Methyl red negative (-ve), Voges Proskauer test positive (+ve), citrate utilization tests positive (+ve), fermentation test (+ve), catalase (+ve), and oxidase test were the biochemical test features that were detected (-ve)[18]**.**
P. aeruginosa colonies are colorless indicating lack of fermentation on EMB and incubated at 35 °C within 48 h. Identification by biochemical tests as following; oxidase (+ve) however, some strain particularly the mucoid ones display a slow oxidase reaction and Catalase (+ve),indole (-ve), citrate (+ve), urease (-ve), nitrate Reduction (+ve)Methyl red negative (-ve) and Voges Proskauer test (-ve) [19]. While, ***Hafnia alvei*** incubated at 35 °C within 48 h on EMB appeared as colorless colonies with the following characters biochemically; Citrate positive (+ve), Flagella flagellated, Catalase positive (+ve), Indole Negative (-ve), Motility Motile, MR (Methyl Red) Variable, Gram Staining Negative (-ve), Positive (+ve) Nitrate Reduction, Oxidative Fermentative Fermentation Shap Rod, Spore Non-Sporing, Oxidase Negative (-ve), Pigment Negative (-ve), and Urease Negative (-ve).

2.3. Isolation and identification of *S. aureus* and*S. saprophyticus* according to ISO [20]

Using mannitol salt agar(MSA Medium)(Techno Pharmchem, Vardhman City Center, New Delhi, India)and incubate the plates at 30°C in an inverted position for 24 to 48 h, the orange colonies represent *S. saprophyticus*, five typical colonies were selected on nutrient agar slant for additional confirmation. Suspected yellow colonies with yellow zones were counted to achieve the total *S. aureus* count. Biochemical assays were used to further identify isolated typical colonies or colonies*S. aureus* (coagulase +ve) or other bacterial species (coagulase -ve) like, *S.saprophyticus.*

Figure 1. Appearance of different isolated microorganisms

2.4. Serological Identification: Nucleic Acid Isolation

According to the manufacturing process, the samples were isolated using the "Quick-DNATM Fungal/Bacterial Miniprep" kit from Zymo research (cat. no. D6005) [21]**.**

Polymerase chain reaction: the primer sequences used for the PCR were 27 Forward (5'-AGAGTTTGATCMTGGCTCAG-3')and 1492 Reverse (5'-TACGGYTACCTTGTTACGACTT -3') and were made with DreamTaq Green PCR Master Mix (2X) (cat# K1081). With a total volume of 25 µl, the procedure is carried out as following; denaturation at 95°C/30 Sec.,followed by annealing at 58°C/ 30Sec and extension performed at 72°C/90 min. then final extension performed at 72°C/7 min and holding at 4°C until using **[**22]**.**

Primer design (Table 1): Using the MegAlign tool, relevant 16S rDNA sequences from the GenBank database were aligned (DNASTAR Inc., Madison, Wis.). Putative genus- and species-specific primers were created based on this alignment [22]**.**

Gel Electrophoresis: Verification of the PCR amplification product's quality and size is done using agarose gel electrophoresis. Utilizing Ultrapure Agarose from Cleaver Scientific and 1X TBE buffer, a 2% gel is created and stained with Safe DNA Stain (Invitrogen, California USA). Each gel well was filled with 4 µl of PCR product. Alongside the samples, a DNA ladder (100-1000) from molecule one was run for 30 minat 100 mV. Using a UV trans-illuminator called the Gel Doc system imager, DNA fragments were seen.

PCR Purification: ExoSAP-ITTM was used to purify the amplified DNA. Mix 5 l of PCR reaction product and 2 µl of ExoSAPITTM in accordance with the manufacturing protocol. The remaining primers and nucleotides should then be incubated for 15 min at 37°C before being incubated at 80°C for 15 min to inactivate the ExoSAP-ITTM reagent.

Cycle sequencing PCR: the PCR reaction for cycle sequencing was performed using the BigDye Terminator v3.1 Cycle Sequencing kit (Life Technologies, USA).

Cycle sequencing PCR: Using BigDye X Terminator, the cycle sequencing purification was carried out (Applied Biosystem, USA).

Sequencing Platform: SeqStudio(Life Technologies, USA) was used for sequencing, and it was run after a medium module.

Sequence Alignment: Sequence analysis by SNapGene version 6.0.2 and extract Fasta format and alignment through an online tool NCBI blast.

2.5. Statistical analysis

Every value is displayed as a mean with standard error. The statistical analysis for this study was performed using **(SPSS16)**. Data were analyzed using the one-way analysis of variance approach (ANOVA test). The significant differences ($P<0.05$).

3. Results

3.1. Statistical Analysis of Different types of microorganisms in Camel Samples

Bacteriological profile of the camel samples revealed the positive aerobic bacteria were about 50/50 (100%) of the total camel sample same result detected in case of Anaerobic, while *Enterobacteriacea*spp.and *Staphylococcus* spp.count were about (70%), (40%) respectively while only about 2/50 (5%) of tested camel sample were have *Pseudomonas* spp.

Statistical analysis for different types of micro-organisms (CFU/g) in the minced camel samples discussed on Table (2) were; the total aerobic counts reported about; 9.0×10^2, 20.5×10^4, $4.2 \times 10^4 \pm 1.7 \times 10^4$as minimum, maximum, mean ±SE values respectively while, about; In the instance of the total anaerobic count, the minimum, maximum, mean, and standard error of the mean values were found to be 1.0×10^3, 1.9×10^5, 3.8×10^4, and 1.5×10^4, respectively.*Enterobacteriacea*spp. showed about; 1.06×10^4, 4.3×10^4, $2.9 \times 10^4 \pm 4.5 \times 10^3$as minimum, maximum, mean ±SE values respectively while, about;1.6×10^4, 3.3×10^4, $2.5 \times 10^4 \pm 2.4 \times 10^3$were detected as minimum, maximum, mean ±SE values respectively in case of *Staphylococcus* spp. counts.

Table 2. Statistical analysis for different types of microorganisms (CFU/g) in Camel samples

Micro-organisms	Minimum	Maximum	Mean	SE±
Aerobic count	9.00×10^2	20.5×10^4	4.2×10^4	1.7×10^4
Anaerobic count	1.00×10^3	1.90×10^5	3.8×10^4	1.5×10^4
*Enterobacteriacae*spp.	1.06×10^4	4.30×10^4	2.9×10^4	4.5×10^3
Staphylococcus spp.	1.60×10^4	3.30×10^4	2.5×10^4	2.4×10^3

3.2. Comparison with microbiological criteria for foodstuffs

The permitted level for various meat products falls between 5×10^5 and 5×10^6CFU/g, as per Saudi Arabia's microbiological requirements for foodstuffs. All samples should be free of any foodborne pathogens in the case of total aerobic count and anaerobic, 10^2 -10^3 CFU/g in the case of *Enterobacteriacae*, and 10^2 -10^3CFU/g in the case of *Staphylococcus*.

Comparison with the microbiological standards for food, as seen in Figure (2), revealed that all of the camel meat samples examined were acceptable for human consumption.

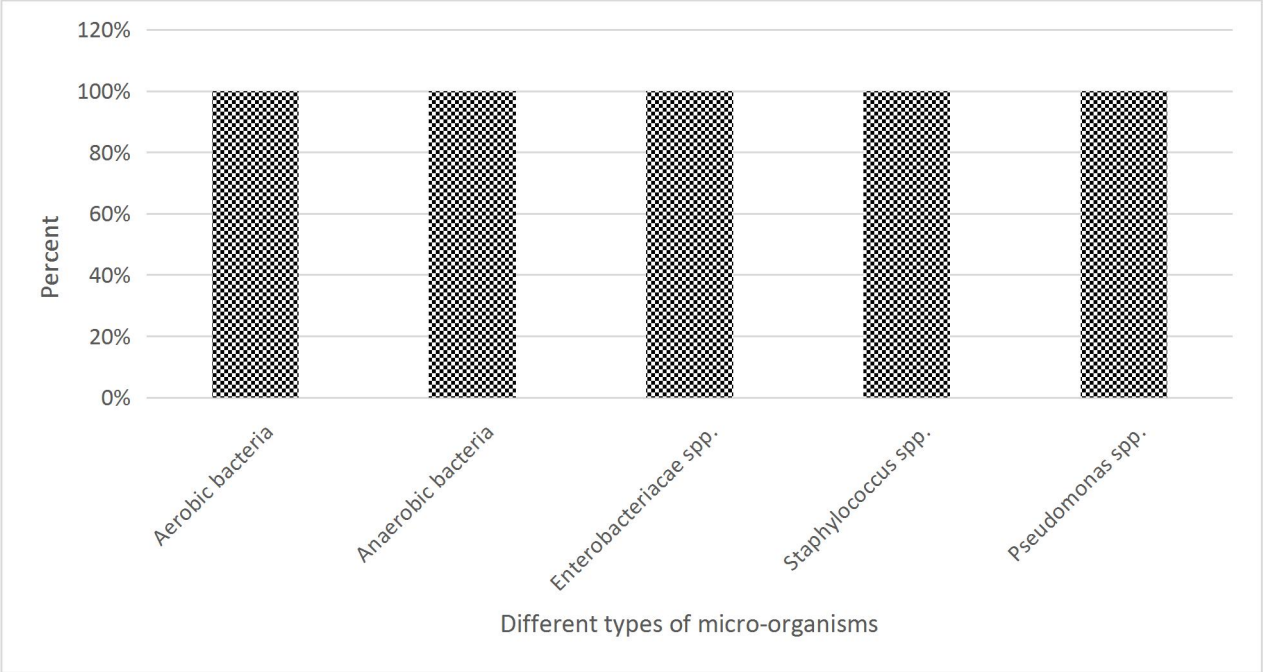

Figure 2. Comparison with microbiological criteria for foodstuffs

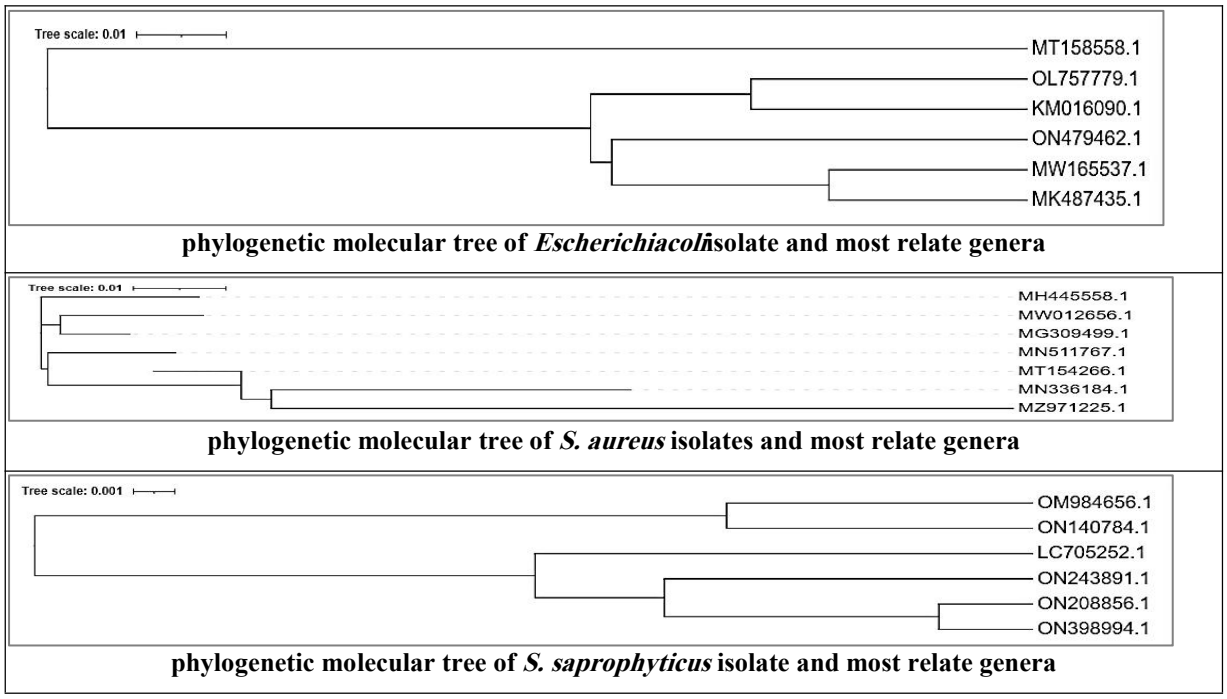
3.3. Molecular Identification of isolated microorganism:

Figure (3) show that thePCR identification was as following; *E. coli, Staphylococcussaprophyticus, Staphylococcus aureus, Klebsiella pneumoniae, Pseudomonas aeruginosa, Hafnia alvei*were 2/12 (16.6%) for all microorganisms.



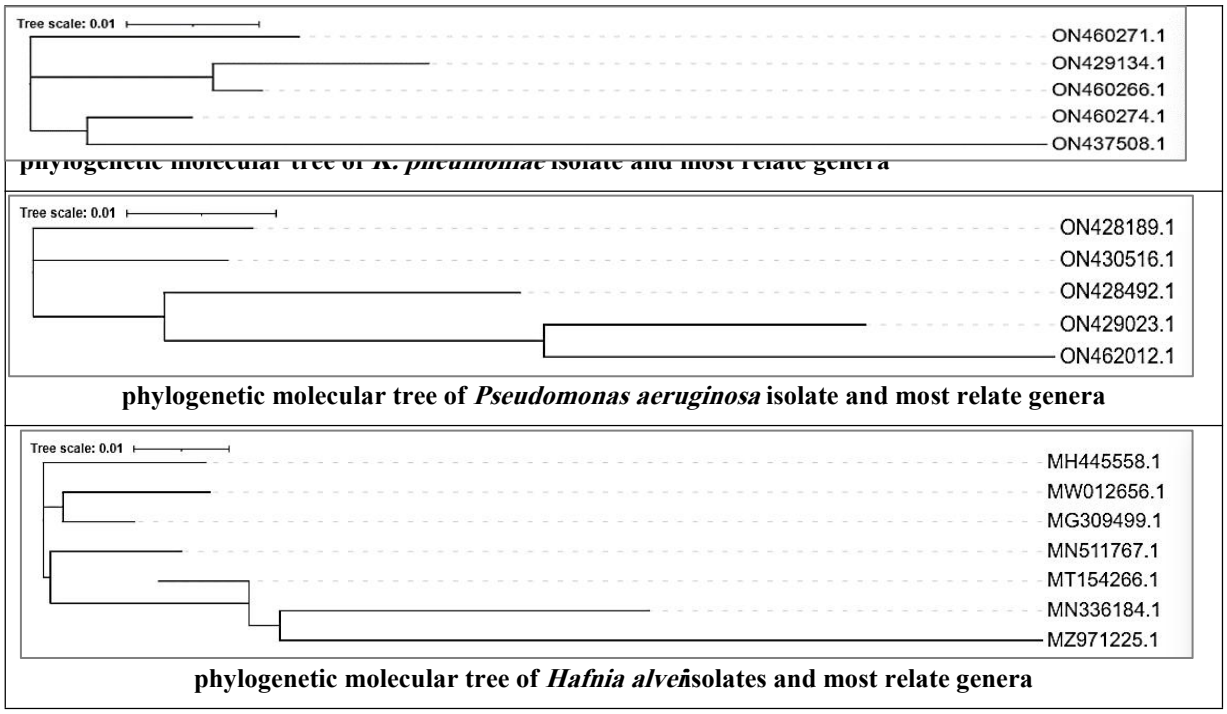


Figure 3. Molecular Identification of isolated microorganism

4. Discussion

Camel meat has been the most neglected animal as the meat source over the years whether its richness in nutrient elements specially protein [23-24]. This neglection not including the study of the nutritious compounds only but including the microbiological profile also [25-26].

Bacteriological analysis of the camel samples showed that the positive aerobic bacteria made up around 50%(100%) of the whole camel sample, while only about70%,40%, and 2/50(5%), respectively, of the tested camel samples contained *Staphylococcus* spp. and *Pseudomonas* spp., respectively. of the camel samples revealed; the positive aerobic bacteria were about 50/50 (100%) of the total camel sample same result detected in case of Anaerobic, *Enterobacteriacea*spp. count while, only about (70%), (40%) of tested camel sample have *Staphylococcus* spp. while only about 2/50 (5%) of tested camel sample were have *Pseudomonas* spp. Statistical analysis for Different Types of Micro-organisms (CFU/g) in the minced camel samples were; the total aerobic counts reported about; 9.0×10^2, 20.5×10^4, $4.2 \times 10^4 \pm 1.7 \times 10^4$ as minimum, maximum, mean ±SE values respectively while, about; 1.0×10^3, 1.9×10^5, $3.8 \times 10^4 \pm 1.5 \times 10^4$were detected as minimum, maximum, mean ±SE values respectively in case of total anaerobic count. *Enterobacteriacea*spp. showed about; 1.06×10^4, 4.3×10^4, $2.9 \times 10^4 \pm 4.5 \times 10^3$as minimum, maximum, mean ±SE values respectively while, about;1.6×10^4, 3.3×10^4, $2.5 \times 10^4 \pm 2.4 \times 10^3$ were detected as minimum, maximum, mean ±SE values respectively in case of *Staphylococcus* spp. counts. Comparison with microbiological criteria for foodstuffs [27]declared that; all tested camel meat samples were within permissible limit and fit for human consumption. PCR identification mentioned in table and figure (4.1.4) were as following; *E. coli, Staphylococcussaprophyticus, Staphylococcus aureus, Klebsiella pneumoniae, Pseudomonas aeruginosa, Hafnia alvei*were 2/12 (16.6%) for all microorganisms.

The abattoir and butcheries' internal sanitary conditions have always been gauged by the overall viable count. **Hassen *et al.*** [1] found a higher result when they examined Ethiopian camel meat samples and discovered 4.67.017 log10CFU/g aerobic plate counts. Poor handling and hygiene methods that caused cross contamination and recontamination of meat were blamed for the increased Activated Protein C (APC)APCs found in this study [28]. The APC values from the meat samples in the neighborhood butcheries, however, were higher than those from abattoirs but lower than the recommended amount of fewer than 6.00 log10CFU /g/cm2 recommended by the International Commission on Microbiological Specifications for Foods (ICMSF, the Commission). A high microbe count that is greater than 7.00 Log CFU/g of Total Plate Count (TPC) is a signof meat deterioration and significant health risks. Meat hygiene must be rapidly improved because the total plate count for raw meat surpassing 5 log10 CFU/g was unacceptable [29]**.**

The 60% of the samples in this investigation showed APC levels greater than 5 log10CFU/g, which is a sign of severely infected meat. The butcheries house's significantly higher mean APCs than the abattoirs indicate that meat is handled in an excessively unhygienic manner, that storage and transportation conditions are of lower quality, and that the butcheries house provides an environment that is conducive to the growth of aerobic bacteria. The current study's findings are significantly more polluted than those from **Al-Dughaymand Yassein**[30]. Our research found that the surface camel carcasses had mean aerobic plate counts of $4x10^3$, $5x10^3$ and $6.2x10^3$ CFU/cm^2, respectively, before skinning, after skinning, and after preparation and stamping. The increased amount of aerobic plate count seen in this study is consistent with other studies [31].

This study's outcome was less favorable than *E. coli* was found in fresh meat from the abattoir and (22.2%) butchers in Mekele, Ethiopia, according to **Haileselassie *et al.*** [32] research. *E. coli* contamination rates from raw meat were high at the butchers (38.2%) and the abattoir (55.9%)[33]. These results complement **Mohammed, *et al.*** [6] conclusion that *E. coli* was isolated from staff members' hands at the butcher shop and the abattoir in Ethiopia, respectively, in percentages of 46.2% and 52.6%. Higher results were reported by **Sternišа*et al.*** [34]. who examined 80 camel meat carcasses from Egyptian abattoirs and found that the mean *Enterobacteriaceae* counts were around ($9.77x10^7$;$3.44 x10^7$), higher rates of *Klebsiella pnumoniae* (35%), and approximately 5% of *E. coli* isolates. Almost same outcomes were reported by **Wie,** [35]**.** From 68 samples of camel meat, **Hassen *et al.***[1] evaluated the hygienic practices used in Ethiopia for handling raw camel meat. *S. aureus, E. coli*, and *Salmonella* spp. were found in 12 (35.3%), 16 (47%) and 8 (23.5%) of the raw camel meat samples, and in 19 (55.9%), 22 (64.7%) and 10 (29.4%) of the butcheries, respectively. On the other hand**, Babiker *et al.*** [36]. established that camel carcasses in a slaughterhouse in Sudan were contaminated with microorganisms. *Pseudomonas* spp. (18.69%) had the highest TBC and *Salmonella* spp. (1.62%) had the lowest. The TBC varied from 12 x 10^3cfu/ml to 1, 2 x10^3CFU/ml.

Alebie*et al.*[37]found about *Staphylococcus aureus* (8.7%), *Escherichia coli* (6.52%), *Kebsiellapnumoniae*(4.35%) from camel corpses in Ethiopia. This finding is less than that made public by **Regassa *et al.***[38]. and **Suheir *et al.*** [39] who discovered a prevalence of 36.87% and 39.4% in camel herds in Ethiopia and Sudan, respectively.This result agrees with the findings of **Mengistu *et al.*** [40]. which is 9.6% and 2.1%, for *E. coli*, *Klebsiella pnumoniae* respectively. Another study performed by **Osman *et al.*** [41]. Using PCR to identify *Pseudomonas* species, it was discovered that 10/100 samples of Egyptian camel flesh contained *Pseudomonas* species, with *Pseudomonas aeruginosa* accounting for 8/10 and *Pseudomonasfluorescens* for 2%. In addition to being resistant to four to eight different classes—four to six different antibiotics—the isolates were also multidrug resistant.

Gram-negative bacillus *Hafnia alvei* is a member of the *Enterobacter* ales order's newly proposed Hafniaceaefamily [42-43]. *H. alvei* can be found in a variety of natural settings, including fish farms, rivers, and streams that have been contaminated [44]. This bacterium is also common in the digestive tract of many animals[26]. Several animal species, including mammals, fish, birds, and insects, have been thought to be susceptible to some *H. alvei* strains, which are considered opportunistic pathogens [45]**,** and are also suspected to cause a variety of disorders in humans [46]. According to taxonomic identification, several *H. alvei* strains were related species' strains of *Escherichia*, Citrobacter, *Salmonella*, and *Serratia* [47-48].All systems were used to identify strains of *H. alvei* isolated from food with satisfactory results [49-50]**.** It's significant because some *H. alvei* strains found in various foods contain genes for toxins like the verodoxin and the heat-stable *E. coli* toxin. *H. alvei*include verodoxins, as demonstrated by in vitro studies against a tissue culture cell line made from monkey kidney epithelial cells[51]**.** *H. alvei* was also listed among the microorganisms that contribute favorably to food fermentations, and in some circumstances, it appears to play a significant role in food spoiling[52].

5. Conclusion

The presence of bacterial pathogens in camel meat poses a significant risk to consumers, as these pathogens can thrive and reproduce under favorable conditions. The growth of bacteria on meat surfaces can lead to a decline in product quality and potential health hazards. In addition to being a rich source of protein and essential amino acids, camel meat should also contain vitamins and minerals such as vitamin B, vitamin A, zinc, and iron to provide a complete diet. The isolation and identification of bacterial pathogens, including *E. coli, Staphylococcus aureus, Salmonella sp, Klebsiella pneumoniae, Pseudomonas aeruginosa, and Hafnia alvei*, were carried out using bacteriological plating, microscopic inspection, and serological testing. The camel meat samples analyzed showed the presence of *Staphylococcus spp.* in approximately 70% and 40% of the samples, respectively. Positive aerobic bacteria accounted for around 50% of the entire sample, while only 5% of the samples tested positive for *Pseudomonas spp.* The microbiological criteria for food were met by all camel meat samples, indicating their suitability for human consumption. To combat the presence of bacterial pathogens such as *E. coli,*

Staphylococcus aureus, Staphylococcus saprophyticus, Pseudomonas aeruginosa, Klebsiella pneumoniae, and *Hafnia alvei*, the use of Arabic gum extracts was investigated as a potential solution.
