ABSTRACT
Two field trials were carried out during 2014/2015 and 2015/2016 seasons at the El-Maghara Research Station-Desert Research Center., to study the effect of algae extract foliar application as partial replacement for chemical fertilization on vegetative growth, fruits yield, essential oil and its main components as well as chemical constituents of Dutch fennel under Sinai conditions. Treatments were the combination of five fertilization levels (full recommended dose of NPK only, 75, 50, 25% of the recommended NPK plus spraying with algae extract and spraying algae extract only), as treatments were arranged in a randomized complete blocks design with three replications for each treatment. The results showed that, application of T2 (75% of the recommended NPK plus algae extract) increased plant height, number of umbels, fresh and dry weights / plant and maximized the essential oil yield compared to other treatments. However, the least amount of essential oil yield was obtained in plants treated with spraying algae extract only. Application of T2 also increased the concentration of N, P and K in plant tissues, Meanwhile, T5(spraying with only algae extract) led to the lowest values compared other treatments in both seasons. As general the main chemical constituents of Dutch fennel essential oil were trans-anethole, estragole, fenchone, limonene, alpha-pinene. Keywords: Foeniculum vulgare, algae extract, volatile oil, trans-anethole, estragole.

INTRODUCTION
Fennel (Foeniculum vulgare Mill), Family Apiaceae, is considered an important economic crop, used in the domestic market as important spice, in pharmaceutical industries, and is ranked the first in the list of Egyptian exports of herbs and spices (EMAP, 2011-2012). Moreover, fennel fruits possess anticancer activity (Anand et al., 2008) and also has an antimicrobial, anti-inflammatory effect (Ali, 2002). Thus, it can be utilized as carminative, diuretic, expectorant and stimulant, antispasmodic, stomachic and sedative (Mahfouz and Sharaf-Keldin, 2007). It is also used in gastroenteritis, hernia, indigestion and abdominal pain according to (Boulos,1983 and Lawless, 1997). The flavor of fennel oil depends upon its main constituents: fenchone, estragole which is a bitter tasting element and anethole with a sweet anise-like flavor (Braun and Franz, 1999). Proportions of these ingredients vary according to strains and region as mentioned by (Osman and Abd El-Wahab, 2003). The local variety of Egyptian fennel contain higher percentage of estragole (20-60%) as recorded by (Shahat et al., 2011); accordingly, exports of organic fennel from Egypt have been banned in some products in the EU markets (Yousef and Omneya, 2014). Several attempts have been made since octets of the last century to introduce new strains of sweet fennel, which featuring with proportion height of anethole to more than 50%, and less estragole proportion less than 10% (Shalaby et al., 2011 and Abd-Allah, 2012). Dutch fennel (Foeniculum vulgare sp. Vulgare) is a new strain of fennel imported from Holland by Sekem Co. and has been tested in different regions of Egypt and was marked for superiority in the oil yield and chemical components compared to other cultivated strains with an average ratio of anethole up to 75%.

For many reasons, the government encourages the expand in agriculture activity with the emphasis of medicinal and aromatic plants in the region of Sinai. Thus, the present research aimed to investigate the production of Dutch fennel using Spirulina algae extract foliar application as partial replacement for chemical fertilization under Sinai sandy soil conditions.

MATERIALS AND METHODS
1. Location and plant material
The present study was carried out during the two successive seasons of 2014/2015 and 2015/2016 at the El-Maghar Research Station- Desert Research Center (latitude 30.35° N, longitude 33.20° E and 200 meters above sea level 90 km South El-Arish City) in the middle of Sinai (North Sinai Governorate). The physical and chemical properties of the experimental soil are presented in Tables (A and B). Underground water was used as irrigation source; chemical analysis of the underground water is presented in Table (C).

2. Soil preparation and seed sowing:

During soil preparation, a sandy soil was amended with botanical compost from local source at 10 m$^{-3}$/fed with adding calcium superphosphate immediately before planting in each season in only one dose during the preparation of the soil. The distances were 50 cm between hill and 75 cm between rows, under drip irrigation system within 50 cm between drippers with a rate of 4 liter/hour/hill every two days in the whole period of both seasons. Three to five seeds were sown into hills at 18th October in the first season and 21st October in the second season within the drippers of irrigation lines and irrigation was done immediately after sowing. After germination, seedlings were thinned to two plants/hill.

Chemical fertilizer sources

Ammonium sulphate 20.5% N was used as a source of nitrogen, calcium superphosphate 15% P$_2$O$_5$ was used as P source and potassium sulphate 48% K$_2$O was used as K source.

3. Fertilization treatments

T1. The recommended dose (85 kg N, 32 kg P and 48 kg K/feddan) after (Ali, 2002) was used as a control treatment.

T2. 75% of recommended dose plus alga extract.

T3. 50% of recommended dose plus alga extract.

T4. 25% of recommended dose plus alga extract.

T5. Alga extract without chemical fertilizer.

Application time:

Application with calcium superphosphate was conducted immediately before planting in each season in only one dose during the preparation of the land for agriculture. Nitrogen and potassium fertilizers were applied in three equal doses at 30, 60 and 90 days after seed sowing in both seasons. Application of algae extract was done twice at two stages; the first stage was 60 days after seed sowing in both seasons. Three to five seeds were sown into hills at 18th October in the first season and 21st October in the second season within the drippers of irrigation lines and irrigation was done immediately after sowing. After germination, seedlings were thinned to two plants/hill.

Algae extract:

Algae extract was obtained from Algae Production Unit at the National Research Center as an extract of the algae Spirulina platensis. Analysis of the used algae extract is represented in Table (A). The algae extract was applied as foliar application in the early morning before sunrise at concentration 1/200 l water/fed.

Growth evaluation:

Harvesting was carried out in the second week of May 2015 and 2016. Harvest was done early as possible and plant height (cm) was recorded before harvest using measuring tape. After harvest, yield characteristics recorded were fresh and dry weights/plant (g), number of umbels/plant, fruit yield/plant (g) and/feddan (ton), weight of 1000 fruits(g).

Essential oil productivity: Essential oil percentage of fennel fruits was determined by hydro distillation for 3 h using the method of Guenther, (1961), the oil percentage was used to calculate essential oil yield/plant (ml), and feddan (l). The extracted volatile oil was dehydrated over anhydrous sodium sulphate and stored in a refrigerator until GC/MS analysis.

Chemical analysis

Chlorophyll a, b, total chlorophyll and Carotenoids (mg/g f.w.) were determined in leaf fresh samples at 90 days after seed sowing in both seasons as described by as described by (Saric et al., 1967). N, P and K percentages as well as total carbohydrates in the dry herb were estimated at flowering time. Nitrogen was determined by modified micro Kjeldahle method as described by (A.O.A.C. 1970). Phosphorus was colorimetrically determined using the method described by (Murphy and Riley, 1962) using spectrophotometer at 882 µv. Potassium percentage was estimated using flame photometry according to (Cottenie et al., 1982). Total carbohydrates in the dry leaves was determined by using a colorimetric method of (Herbert et al., 1971).

Essential oil GC/MS analysis:

The GC-MS analysis for oil samples from the second season was carried out at the Central Laboratory of National Research Center, Giza. Essential oil GC/ Mass analysis was performed using a Hewlett-Packard 5890 A series 11 instrument equipped with flame ionization detector (FID) and a carbon wax fused silica column (50 m x 0.25 mm, i. d., film thickness 0.32 µm). Initial column temperature was 50 Cº and held for 3 minutes, then raised to 60 Cº by rate 3.0 Cº / minute and raised to 260 Cº by rate 3.0 Cº /minute and hold at 260 Cº for 5 minutes. The volatile oil components were identified by comparing their retention times and mass spectrum with those of standards, NIST library of the GC-MS system and literature data.

Experiment layout and statistical analysis

Treatment of this experiment were arranged in a randomized complete block design. Each treatment contained three replicates of 10 plants. Collected data were analyzed using MSTAT C Program, (Bricker, 1991) Means were compared using LSD test at 0.05 level according to (Snedecor and Cochran, 1980).

RESULTS

Vegetative growth characters:

Plant height: The presented results in table (1) showed that, plants treated with 75% NPK plus algae extract T2 had the highest growth parameters compared to other
treatments. Meanwhile, plants treated with full NPK dose only T1 came in the second place. Treatment T5 of spraying algae extract only recorded the shortest plants compared to other treatments in both seasons.

Means within the same column for each trait significantly differ from each other according to the LSD test at p<0.05. T1 (full recommended dose of NPK), T2 (75% NPK recommended dose plus algae extract), T3 (50% NPK recommended dose plus algae extract), T4 (25% NPK recommended dose plus algae extract), T5 (algae extract only).

**Plant fresh weight (g):** It is evident from data presented in Table (1) that, plant fresh weight was positively increased due T2 treatment in both seasons (602.20 and 677.80 g/plant), respectively without any significant differences neither with T1 nor with T3 treatments in the first season. Individual treatment of T5 resulted in the least plant fresh weight among all treatments.

**Plant dry weight (g):** The largest amount of plant dry weight occurred with the application of T2 treatment as shown in Table (1) compared to other treatments. Following the same pattern, application of individual algae extract resulted in the lowest values for plant dry weight in both seasons in comparison with all other treatments.

**Number of umbels:** Data presented in Table (2) show that, number of umbels took the same direction of plant height, T2 treatment gave the highest number of umbels compared to other treatments, while treatment of T5 recorded the lowest number of umbels compared to other treatments in both seasons.

**Fruit yield/plant (g) and/feددdan (ton):** The highest fruit yield 81.11 g/plant and 1.82 ton/feددdan in the first season and 81.67 g/plant and 1.83 ton/feددdan in the second one was obtained by T2. However, the lowest fruit yield 45.00 g / plant or 1.01 ton / feددdan in the first season and 46.11 g / plant or 1.03 ton / feددdan in the second season were obtained with T5 in both season as shown in Table (2).

Means within the same column for each trait significantly differ from each other according to the LSD test at p<0.05. T1 (full recommended dose of NPK), T2 (75% NPK recommended dose plus algae extract), T3 (50% NPK recommended dose plus algae extract), T4 (25% NPK recommended dose plus algae extract), T5 (algae extract only).
Oil yield/plant (ml) and feddan (f): It is evident from data presented in Table (3) that, the highest oil yield of 1.64 ml/plant and 36.80 l/feddan in the first season and 1.67 ml/plant and 37.37 l/feddan in the second one was obtained by T2 treatment. The lowest oil yield of 0.70 ml/plant and 15.50 l/feddan in the first season and 0.71 ml/plant and 16.00 l/feddan in the second one resulted with the T5 treatment compared to other treatments in both seasons.

Pigments content: Data presented in Table (5) indicate that, the pigments content (chlorophyll a, b, total chlorophyll, and carotenoids) recorded their lowest values when plants were treated by T5 treatment. However, treatments didn’t record any significant effect and the highest values in this concern was recorded for plants treated with T2 treatment which showed a significant increase in both chlorophyll and carotenoids contents in the both seasons.

Nutrient elements (%): Table (4) also showed that the highest N, P and K percentages were obtained by fertilizing the plants with T2 treatment, while the lowest percentages resulted from T5 treatment compared to other treatments in both seasons.

Total carbohydrates (%): The results presented in Table (4) showed that there was significant increase in total carbohydrates percentage due to T2 treatment (26.36% and 26.37% in both seasons, respectively). T5 treatment recorded that the lowest carbohydrates percentage (19.93% and 20.02% in both seasons, respectively) compared to other combinations treatments in both seasons.

Volatile oil GC/ Mass analysis: The analysis of the essential oils in Dutch fennel (Table 5) showed the presence of 14 compounds with the presence of trans-anethole as the main component followed by estragole. The highest percentage of trans-anethole (72.16%) was obtained by T2 treatment followed by T1 and T5 respectively. However, the lowest percentage of estragole (38.06%) resulted from T3 compared to other treatments. The lowest percentage of estragole (8.30%) resulted with T2 and in the second place came T5 and T1 respectively. However, the highest percentage of estragole (32.46%) was obtained by T3 followed by T1 and T4 respectively, compared to other treatments.

</table>
| T1 (full recommended dose of NPK), T2 (75% NPK recommended dose plus algae extract), T3 (50% NPK recommended dose plus algae extract), T4 (25% NPK recommended dose plus algae extract), T5 (algae extract only).

**DISCUSSION**

Blue-green algae plays a key role in improving growth of many plants when applied as a bio fertilizer. This evidence was clearly appeared in growth criteria of Dutch fennel presented in Table (1). The performance of Dutch fennel plants, in terms of plant height, fresh and dry weights/plant, were enhanced by algae extract application in both seasons. The use of blue-green algae is known to cause many beneficial effects on plants as they contain growth promoting hormones (IAA and cytokinins) trace elements (Fe, Cu, Zn, Co, Mo, Mn, and Ni), vitamins and 62% of the amino acids (Challen and Hemingway, 1965).

The stimulatory effect of blue-green alga extract could be due to its high content of macro and micro elements. However, micronutrients fertilizer has only the effect of encouraging roots to absorb more nutrients from the soil medium as mentioned by (Shaaban and Mubarak, 2000), as well as it contains the whole spectrum of natural mixed carotene and xanthophyll phyto pigments which are considered as the richest...
natural source of vitamin B-12. Also, it contains high content of free amino acids. In addition to the presence of high levels of various plant hormones such as auxins and cytokinins, which are considered important and vital for raising the plants production and increasing the ability of plants to withstand various stress conditions as reported by (Aly and Esawy, 2008 and Kemka et al., 2007).

These results were in agreement with those obtained by (Abd El-Wahab et al., 2016) on *Origanum vulgare* L. who found that, the significantly highest increase for growth characters resulted when plants were treated by algae extract plus biofertilizer plus 15m³ compost and (Sahu et al., 2013) on coriander (*Coriandrum sativum*) who showed that, the highest plant height and dry weight plant was obtained by using the treatment 100% K and 75% NP along with *Azotobacter*, *Azospirillum* and PSB.

Further studies claimed that algae extract stimulate growth as it contains a series of plant growth promoters. Of these, (Rama Rao, 1991) reported that, aqueous extract of *Sargassum wightii* when applied as a foliar spray on *Zizyphus mauritiana* showed an increase in yield and quality of fruits. This may the attributed to the high protein content of the algal extract which split into natural plant amino acids involved directly in the metabolism (Shaaban, 2001). Two nutrient sources might be considered in the case of algal extract treatments. One source is the algal extract itself and the second is its positive effect on the nutrients uptake by the plant roots (Shaaban, 2001).

These results were in harmony with those reported by (Sahu et al., 2013) who indicated that, the highest number of umbels / plant, weight of 1000 seed and seed yield were obtained by using the treatment (100% K and 75% NP along with *Azotobacter*, *Azospirillum* and PSB) on coriander (*Coriandrum sativum*) and in the same the regard (Abd El-Wahab et al., 2016) recorded that, the use of algae, with biofertilizer plus 15m³ compost on *Origanum vulgare* L. recorded that, the highest treatment of yield characters, also the highest oil yield resulted with the treatment of algae, with biofertilizer and compost at 15m³. The same effect of algae extract was retired on some Russian dill varieties (Toaima et al., 2017). The interaction results indicated that cultivation of Aurora variety combined with foliar spray of 1.5 liter of blue-green algae extract of *Spirulina platensis* produced significantly maximum seed yield / plant and / feddan, volatile oil yield / plant and / feddan (cultivation of local type without foliar spray of algae extract) which recorded the lowest parameters.

 Assassجية الشجرة الهولندية للاستبدال الجزءي للتسهيد المعدني باستخدام الرش مستخلص الطحالب حسنى حمدى اللبان1، محمد إبراهيم فتحي2، رانية مرتضى خاطر1 و سامح حسن الجيبي1

1 قسم البيئات – كلية الزراعة – جامعة الهرم
2 قسم البيئات الطبية والطبيعة – مركز بحوث الصحراء

تم إجراء تجربتين خلال عامي 2014/2015 و2016/2016 بمحاطة بحوت الصحراء – مركز بحوث الصحراء، دراسة تأثير مستخلص الطحالب الورقية كبدائل جزئية للتسهيد المعدني على النمو الخضري، وزروع الطماطم وكمياتهما الرئيسية وكذلك المكونات الكيميائية للشجرة الهولندية تحت ظروف سناء. وأجريت التحري في خمس معاملات (إضافة الدفعة الكاملة من التسهيد المعدني المصى بها إضافة 75 و25 % من التسهيد المعدني + الرش مستخلص الطحالب بمعدل لتر/200 لتر ماء للفردان + ورفر). في حالة استخدام الزهور في دراسة، سُميت معاملات: LED (أي زيادة في كمية النور الخضري) ومستخلص الطحالب (أي زيادة في كمية مستخلص الطحالب). في حين أن إعطاء محتوى زيت للفردان صدر من النباتات التي تم استخدامها والثدي الزمني النمو النباتي (T2)، و أيضا استخدام الأ aime العاملة في T2 أدى إلى زيادة النمو النباتي. و認めت هذه النتائج مستخلص الطحالب والثدي النمو النباتي (T2) ومحتوى زيت للفردان (T2) أثناء استخدام الأ aime العاملة في T2، وإلى زيادة النمو النباتي. وتميزت النباتات (T4) وسهولة انطلاق النباتات. وپذيرفة النباتات (T5) وسهولة انطلاق النباتات. وپذيرفة النباتات. وپذيرفة النباتات Was زيت الزيتون النباتي، وأيضا استخدم الأ aime العاملة في T5. وذو مناخ نباتي، وپذيرفة النباتات. وپذيرفة النباتات. وپذيرفة النباتات. وپذيرفة النباتات
