Evaluation of Yield, Fruit Quality and Molecular Diversity for Three Grape Cultivars under New Valley Conditions

Bashandy, T.^{1*}; S. Kamel¹ and H. Ferweez²

¹ Department of Genetics, Faculty of Agriculture, New Valley University, New Valley, Egypt.
² Food Sci. and Techno. Dept., Fac. Agric. New Valley University, Egypt.

ABSTRACT

The current investigation was performed to evaluate the performance and DNA molecular analysis of three grape cultivars under the New Valley governorate, Egypt conditions. Most of the evaluated traits significantly varied among the cultivars. Superior cultivar had the best performance in cluster trait (weight, length and width), berries trait (number per cluster and 100 berries weight) and the total yield per vine. On the other hand, Flame cultivar overtopped in some quality traits (Total Soluble Solids, reducing and total reducing sugars). Molecular analysis was performed by using start codon targeted (SCoT) and inter-simple sequence repeats (ISSR) markers. The detected polymorphism was 68.38% and 41.84%, respectively. The polymorphism information content (PIC) for SCoT and ISSR markers was 0.29 and 0.19, respectively. Thus, SCoT marker was more informative. In contrast, the obtained dendrogram by ISSR showed a better clustering pattern than the SCoT marker.

Keywords: cultivar; genetic diversity; grape; molecular markers.

INTRODUCTION

Grape (*Vitis vinifera* L.) is one of the world's most important fruit crops. It is the second fruit after citrus regarding its productivity but classified as the third major crop according to its cultivated area after citrus and banana. In Egypt, the grape productivity is about 1.7 million tons and the cultivated area is around 196,993 feddans (FAO, 2017). In the past decade, it was almost cultivated with Thompson seedless and Romi Ahmar cultivars. Recently, many cultivars have been introduced to Egypt (El-Morsy *et al.*, 2017).

New valley governorate is 1000 km fare from Cairo in the western desert. Grape is the second favorite fruit after Dates in it. Nevertheless, grape cultivation is still limited although the grape is one of the most successful fruit crops that can be cultivated in the newly reclaimed desert lands. Therefore, much grape quantity is imported from other governorates. However, this work could be contributed to the availability of cultural information regarding the cultivation of grapes in the New Valley governorate.

Phenotypic characterization has widely been used to evaluate the performance of different genotypes under unfavorable conditions (Cantini *et al.*, 1999). However, the obtained results often including the environmental effects too (Kumar, 1999). DNA Molecular markers are a good method to improve the ability of genetic diversity evaluation among genetic resources. They are not influenced by environmental conditions. During the last decade, ISSR PCR-based molecular marker has been developed to use a single primer from a sequence repeats usually 16 to 25 pb long, to amplify the region inter microsatellite sequence (Zietkiewicz *et al.*, 1994). Furthermore, at the beginning of the 21th century Start codon targeted (SCoT) markers have been used, based on the short conserved region flanking the starting codon ATG of a gene (Collard and Mackill, 2008; Xiong *et al.*, 2011). Both ISSR and SCoT are dominant markers. They have widely been used in the detection of genetic diversity among different genotypes (Guo *et al.*, 2012; Bashandy, 2016).

The main aim of the current investigation is to evaluate the performance of three grape cultivars under the natural conditions of New valley governorate, Egypt using field evaluation and DNA molecular marker analysis.

MATERIALS AND METHODS

The current study was conducted during two successive seasons of 2017 and 2018 on six years-old grapevines of three seedless grape cultivars namely Early Sweet, Flame and Superior (Table 1). They were grown at Afak farm located at Balat, New Valley governorate, Egypt. The vines were planted at 3x1.5 meters apart in silty clay soil and the irrigation was by a drip irrigation system and supported by Gable system. Each cultivar carry 30 cluster per vine after manual slipping of clusters. The experiment was conducted in a randomized complete block design with three replicates for each cultivar. All farming management practices were carried out as recommended. At ripening stage, three clusters were randomly picked up from each vine and we estimated some morphological traits (i.e., cluster weight (g), cluster length (cm), cluster width (cm), number of berries per each cluster, 100 berries weight (g), berry weight (g) yield per vine (kg) and some quality traits (i.e., total soluble solids (TSS), reducing sugars (RS), non-reducing sugars (NRS), total reducing sugars (TRS) according to A.O.A.C. (1985) and pH).

Statistical analysis:

Analysis of variance (ANOVA) for a randomized complete block design according to Gomez and Gomez (1984) was conducted. Least significant differences (L.S.D) were used in mean comparisons. The recorded data were analyzed by using SAS statistical software program.

	/		
Cultivars	Origin	Traits description	Harvest date
Early Sweet	Foreign	Creamy white color, a large round seedless berry and has a highly sweet flavor.	1 May to 15 May
Flame	Foreign	Deep red color, round, sweet, vine-ripened by the sun and early season cultivar.	15 May to 30 June
Superior	Foreign	Obvious green color, a large round seedless berry tends to oval, Bunches abound with berries, crisp texture with a refreshingly sweet taste and early season cultivar.	15 May to 15 June

Molecular characterization:

All the molecular procedures were achieved at the Department of Genetics, Faculty of Agriculture, New Valley University, Egypt.

DNA extraction:

Genomic DNA was isolated from fresh immature leaves of each of the three grape cultures using plant DNA isolation kit (Favorgenv Biotech Corp. Cat. No. FAPGK001) as mentioned in the manufacturer manual. DNA quality and quantity were assessed by spectrophotometer, and then their final concentration was adjusted to 50 ng/µl.

PCR amplification and electrophoresis:

SCoT and ISSR reactions were prepared in a total volume of 25 μ l containing: 12.5 μ l of green PCR Master Mix, 2X (50 units/ml Taq DNA polymerase, 400 μ M of each the four dNTPs and 3 mM MgCl2), 2 μ l of both 10 μ M primer and DNA (50 ng) and finally 8.5 μ l of ddH2o. Amplifications were done in a thermal cycler (Labocon, U.K.). Twelve primers (by metabion) for each marker were used (Table 2). The used program was 94°C for 5 min as initial denaturation, 38 cycles including denaturation at 94°C for 45 sec, annealing for 1 min at 50°C and 48°C for SCoT and ISSR marker, respectively, extension at 72°C for 2 min and a final extension at 72°C for 7 min. PCR amplification products were separated on 1.5% agarose gels in 1×TBE (Tris-Borate-EDTA) buffer at 5 V/cm. Then, they were stained with ethidium bromide.

Data analysis:

We scored 1 for the present band and 0 for the absent band. Jaccard's similarity coefficient was used to estimate genetic similarity. A dendrogram was constructed based on the similarity matrix data by unweighted pair group method with arithmetic average (UPGMA), cluster analysis was calculated using the software computational package MVSP 3.1. program. Some indices namely, polymorphic information contents (PIC), Resolving power (Rp) and Marker Index (MI) were calculated according to Anderson *et al.* (1993), Prevost and Wilkinson (1999) and Powell *et al.*, (1996), respectively.

RESULTS AND DISCUSSION

The performance of the three seedless grapes was evaluated during two seasons. The results in Table (3)

showed that all the studied traits in both the two seasons of evaluations are varied significantly among them exemption the pH, also NRS in the second season.

1- Fruit and cluster traits evaluation:

According to the studied cluster characteristics, Superior cultivar had the highest value (645.9 g, 24.44 cm and 15.78 cm) in cluster weight, length and width, respectively in the first season. For the second season, as well as Superior cultivar was the best and the values were 654.6 gm, 24.11 cm and 15.21 cm, respectively. It followed by both Flame and Early Sweet in both the two seasons. Furthermore, Superior cultivar recorded the highest values of the berries number per cluster and 100 berries weight in both the first season (175.8, 356.0 gm, respectively) and the second season (177.3, 356.9 gm, respectively). Moreover, it was superior over the other cultivars in the total yield per vine in the first season (19.38 kg) and the second season (19.64 kg). All these evaluated characters are the most important indicators for comparing among different grape cultivars and very helpful for crop improvement (Viana et al., 2011). The superiority of superior cultivar in yield is not only due to its superiority in all the above traits but also may be related to its high ability for biotic and abiotic adaptation (Soni et al., 2019). The yield of Flame cultivar per vine was higher than the finding of Soni et al. (2019) who found that its production approximately 4.03 kg. on the other hand, the yield of Early Sweet cultivar was close to finding of El-Salhy et al., 2019 (7.98 kg).

2- Quality parameters assessment:

Some quality traits were assessed for deep comparing among the studied cultivars (Table 3). The TSS significantly differed among the genotypes; all the cultivars had a value higher than the 12.5°Brix (minimum maturity reference value for table grapes, OIV 2008). The maximum value was recorded by Flame cultivar in both seasons (19.80, 20.50°Brix, respectively). Furthermore, the Flame cultivar had the highest value of reducing sugars and TRS in both seasons. These values were 18.83 for RS and 19.18 for TRS in the first season, while in the second season they were 19.17 and 19.58, respectively. Concerning NRS, Superior cultivar had the highest value (0.5167) in the first season, while in the second season the difference among the genotypes was not significant. For the acidity (pH), all the genotypes did not significantly differ. Its value ranged from 3.68 to 3.85 in both seasons. The chemical composition of the grapes is influenced by various factors such as age, genotype and growing conditions (Liu et al., 2006). Flame cultivar had the maximum quantity of TSS and this finding is consistent with Soni et al. (2019). Thus, it is a preferable cultivar, because most the consumers prefer cultivars that have a lower level of acidity and a higher level of TSS (Jayasena and Cameron, 2008). On the other hand, El-Salhy et al. (2019) reported that TSS and reducing sugar values in Early sweet cultivar were 14.9 and 12.11, respectively, these results are close to our results.

3- Molecular characterization:

A- Polymorphism and diversity assessment:

To verify the genetic relationship among the three grape cultivars, SCoT and ISSR molecular analysis were performed (Fig. 1). A total of 117 bands were separated by SCoT marker, their size varied from 140 bp to 1650 bp. The polymorphic bands were 80 bands represented 68.38% polymorphism (Table 4). Regarding ISSR marker, 98 bands were scored and they varied from 130 bp to 1512 pb. Among the total, 41 were polymorphic bands, with 41.84% of polymorphism (Table 4). The SCoT and ISSR markers have successfully been used in the determination of genetic relationships in plants (Bashandy, 2016, Basheer-Salimia and Mujahed, 2019 and Yue *et al.*, 2019). A significant difference was noted between detected polymorphism by the two markers. This difference is because each marker detects different sequences of the genome (Shahlaei *et al.*, 2014). The SCoT marker produced a higher polymorphism than ISSR, this result confirmed the finding of Pakseresht *et al.* (2013), Shahlaei *et al.* (2014), Etminan *et al.* (2016) and Amom *et al.* (2020).

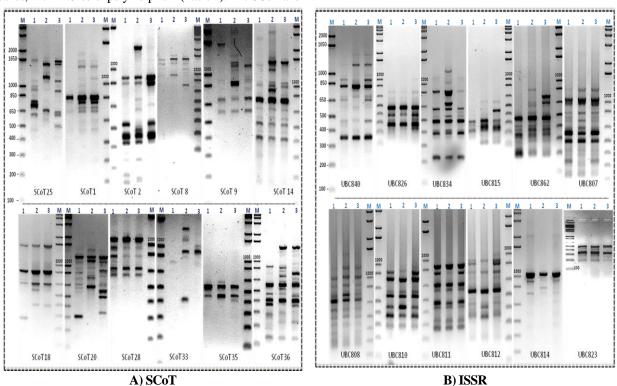

Fig. 1. (A) SCoT banding pattern and (B) ISSR banding pattern of the three grape cultivars. 1, Early Sweet; 2, Flame; 3, Superior, kbp DNA marker.

Furthermore, we calculated the PIC value to measure the informativeness of Polymorphic DNA Markers. The PIC value of the SCoT marker varied from 0.13 to 0.45 with an average of 0.29, but this value ranged from 0.05 to 0.31 with the mean of 0.19 in the ISSR marker. In comparison between the two markers, the SCoT marker gave a higher PIC average than ISSR. Therefore, the SCoT marker has a higher capacity in the detection of polymorphism. Several results are consistent with this result (Pakseresht *et al.*, 2013, Shahlaei *et al.*, 2014 and Amom *et al.*, 2020). On the other hand, the primer resolving power (Rp) was calculated to select the best primer having the highest ability for detection of polymorphism. In the SCoT marker, the Rp value ranged from 1.33 for SCoT28 primer to 8.67 for SCoT25 primers. Regarding ISSR marker, the value of Rp varied from 0.67 to 4.68 for both UBC 810 and UBC 811 and UBC 812, respectively. Moreover, the marker index (MI) was calculated to demonstrate which marker is better at revealing molecular variations. SCoT marker had higher MI value (2.3) than ISSR (0.77) indicating that the SCoT marker had a higher ability for detecting these variations. This is similar to the result of Gorji *et al.* (2011) who performed fingerprinting in some potato varieties and they found that the SCoT marker was more informative and effective than the ISSR marker.

Table4. Polymorphism, Polymorphism InformationContent, Marker index and Resolving powerobtained by SCoT and ISSR markers in thethree grape cultivars.

B- Genetic similarly and relationship:

Furthermore, the degree of similarity among the three cultivars was demonstrated by using Jaccard's similarity coefficient based on SCoT and ISSR data (Table 5). Regarding the SCoT marker, the highest similarity was 0.51 between Superior and Flame, while the lowest similarity (0.40) was between Early Sweet and Flame. Otherwise, the ISSR marker detected the highest similarity (0.74) between Superior and Early Sweet, but Superior and Flame showed the lowest similarity (0.64). The combined results of both markers showed the highest similarity (0.60) between Superior and Early Sweet as the ISSR marker, while Early Sweet and Flame recorded the lowest similarity (0.52) as the SCoT marker.

Also, the dendrograms of genetic distance using SCoT, ISSR markers and combined was constructed (Fig. 2). All the analysis divided the cultivars into two clusters, in SCoT marker the first one contained only Early Sweet, while Superior and Flame were gathered in the second cluster. Regarding both ISSR and combined, the first cluster included Flam only, but the second cluster contained both Superior and Early Sweet cultivars. The constructed dendrograms by both the used markers did not match, because the difference of the detected genetic variations by the two different markers. Many previous works used different markers and exhibited contradictions between resulted dendrograms (Sonia and Gopalakrishna, 2007, Gorji et al., 2011 and Shahlaei et al., 2014). The obtained dendrogram by ISSR marker and the combined gathered both Superior and Early Sweet cultivars in one cluster and this is consistent with that these cultivars are morphologically similar. Therefore, the resulted dendrogram by ISSR exhibited a better clustering pattern than the SCoT marker.

CONCLUSION

The current investigation aimed to evaluate three grape cultivars under the New Valley governorate, Egypt conditions and determine the level of genetic diversity among them. The Superior cultivar surpassed over the two cultivars in the studied agronomic traits, while Flame cultivar was the best in the quality characters. On the other hand, the obtained dendrogram by ISSR was able to classify the cultivars according to their morphological characters.

ACKNOWLEDGMENT

We are grateful to the Faculty of Agriculture, New Valley University, Egypt for the financial support of this work.

تقييم الناتج وجودة الثمار والتنوع الجزيئي بين ثلاثة أصناف من العنب تحت ظروف الوادي الجديد طلعت بشندي 1*، سهير كامل¹ و حسين فرويز محمد ² 1 قسم الوراثة، كلية الزراعة، جامعة الوادي الجديد، الوادي الجديد، مصر ² قسم علوم وتكنولوجيا الأغنية، كلية الزراعة، جامعة الوادي الجديد، الوادي الجديد، مصر

تم إجراء الدراسة الحالية لتقييم الأداء والتحليل الجزيئي للحمض النووي لثلاثة أصناف من العنب تحت ظروف محافظة الوادي الجديد ، مصر. تباينت الصفات التي تم تقييمها بشكل معنويٰ بُبِنَ الأصناف حيثُ كان تُفوق صنف السُوبريور في صفة العقود (الوزن و الطول والعرض) ، و صفةُ الحبوب (الحد لكلُّ عنود ووزن 100 حبة) والمحصول الكلي لكلّ كرمة. من ناحية أخرى ، فقد تقوق صنف الفليم في بعض صفك الجودة (المواد الصلبة النائبة الكلية و السكريك المحلية الم باستخدام الواسملت الجزيئية (SCoT) و (ISSR). حيث كانت النسبة المئوية لتعدد الأشكل المظهرية 68.38 ٪ و 14.8 ٪ على التوالي. و كان المحقوى المعلومةي لتعدد الأشكل المظهرية (PIC) لكل من SCoT و ISSR كان 0.29 و 0.19 على التوالي. وهكذا ، كان واسم الــ SCoT أكثر إفادة. في المقابل، أظهر مخطط التحليل العنقودي وقياس القرابة الورائية للأصناف الذي تم الحصول عليه بو اسطة الو اسم ISSR نمط تجميع عقودي أفضل من الو اسم الجزيئي SCoT.
