# PRODUCTION OF CLEAR APPLE JUICE USING COMMERCIAL PECTINASES <br> Fahem, Nancy I. ; G. A. Mostafa ; H. T. Omran and H. Buckenhueskes* <br> Food Technology Dept., Fac. of Agric., Suez Canal Univ., Ismailia, Egypt. <br> * Hohenheim University, Germany. 

#### Abstract

Clear apple juice was produced from Anna apple cultivar ( Malus spp.) cultivated in Egypt by two stages, pulp enzyming and juice clarification using commercial pectinases. Apple flavour and cramel were added during preparation of clear drinks. Clear apple drinks stored at refrigerator temperature $\left(4^{\circ} \mathrm{C}\right)$, for 5 months were analyzed periodically for chemical, physical, sensory and microbiological characteristics. Data indicated that clear apple juice was processed successfuly using commercial pectinases. Addition of cramel and flavour improved colour, taste, aroma and appearance of natural clarified drink. In respect to chemical chracteristics of the drink, ascorbic acid enrichment is recommended.

Keywords: Clear apple juice, commercial pectinases, pulp enzyming, juice clarification, chemical and physical characteristics .

## INTRODUCTION

Technical enzymes preparations are widely used in the fruit -processing industry to facilitate juice release, increse juice yield and to clarify juices (Schols et al. 1991). A variety of sparkiling clear juices and cloudy juices production depends on pectic enzyme treatment (Pilnik and Rombouts, 1981; Whitaker, 1984 and Voragen and Pilnik, 1998).
Pectic enzymes account for about one-quarter of the world's food enzyme production and most of pectic enzyme preparations are used in the fruit processing industry to increase juice yield and to clarify juices (Rombouts and Pilnik, 1980 and Jayani et al. 2005).

The oldest and still the largest use of pectinases is the fruit juice clarification (Pilnik and Voragen, 1993). Addition of pectinases lowers viscosity and causes cloud particles to aggregate to larger units "break" which sediment and removed easily by centrifugation or (ultra)filtration (Pilnik and Voragen, 1993 and Kashyap et al. 2001)
Commercial pectinases performing well in juice clarification are also suitable for enzyme treatment of the pulp, and in the case of apple, any combination of enzymes depolymerizes highly esterified pectin can be used successfully (Voordouw et al. 1974).
"Anna" apple is cultivated in Egypt. The whole production of apple is displayed in supermarkets for fresh consumption only. Processed apple products should be developed for longer shelf-life and diverse apple products.
The aim of this work is to evaluate new product of "Anna" apple. Clear apple juices using commercial pectinases were produced and evaluated for their

## Fahem, Nancy I. et al.

sensory, chemical, physical and microbiological characteristics during storage for five months at refrigerator temperature.

## MATERIALS AND METHODS

## Materials

Apple fruits were collected at mature stage, from Racheed (El-Behara governorate), then stored at refrigerator temperature $\left(4^{\circ} \mathrm{C}\right)$ untill use. Commercial pectinolytic enzymes; pectinase 444L and macer8TMFJ were obtained from Biocatalysts Limited, Wales, UK. Apple esseence (green apple, 0.017 \%, R9410G) from Delta Aromatic company, El-Geeza, Egypt.

Cramel (E15098001, 0.0125\%, for colouring of apple juice and drink), from Delta Aromatic company, El-Geza, Egypt.

## Microbiological media

Trypton glucose extract agar for standard plate count, was prepared according to Marsall, (1992 a). Standard methods agar for antibiotic plate counts of yeast and mold, was prepared according to Marsall, (1992 b).

## Methods

Production of clear apple juice: Clear apple juice was produced using pectinase 444L ( 300 ppm for mash fermentation and 20 ppm for clarification) and macer8TMFJ ( 250 ppm for mash fermentation and 20 ppm for clarification), as the following:
Mature apple fruits were washed, cored and mashed using moulinex mincer. Apple mashes were treated by pectinases for 30 min at $45^{\circ} \mathrm{C}$. Then raised temperature of the mash to $85^{\circ} \mathrm{C}$ for enzyme inactivation then cooled Mashes were squeezed through double layer opaque cloth. Juice clarification was done using 20 ppm enzyme for 6 hours at $45^{\circ} \mathrm{C}$. Juice filtered through four layer opaque cloth and centrifuged. For preparation of clear apple drinks, clarified juices were adjusted to $14^{\circ}$ Brix with sugar and modified to 1 : 1 dilution with $14^{\circ}$ Brix sugar solution.

## Addition of cramel and apple essence:

Cramel was dissolved in a littel water (w/v \%) with gentle heating, then added to the clear apple drinks to reach a final concentration of 0.02 and $0.035(\mathrm{v} / \mathrm{v} \%)$. Drinks were bottled in a 100 mL - bottles. Apple essence was added to drinks at concentrations of 30ppm, during pasteurization $\left(85^{\circ} \mathrm{C} / 5 \mathrm{~min}\right)$, before sealing, then cooled. Procedures and enzyme treatments were optimized upon preliminary experiments depending on juice yield (v/w\%), TSS, clearance and Sensory evaluation. Seven clear apple drinks were prepared according to the previous flow sheet to be stored at refrigerator temperature $\left(4^{\circ} \mathrm{C}\right)$, for five months:

1. apple juice produced without enzyme treatment (Con)
2. clear apple juice produced by 250 ppm macer8 ${ }^{\text {TM }} \mathrm{FJ}$ for mash
treatment and 20 ppm macer8 ${ }^{\text {TM }} \mathrm{FJ}$ for juice clarification (Em)
3. clear apple juice produced by 250 ppm macer8 ${ }^{\text {TMF }} \mathrm{FJ}$ for mash treatment and 20 ppm macer8 ${ }^{\text {TMFJ }}$ for juice clarification $+0.02 \%$ cramel (Em+Cr1).
4. clear apple juice produced by 250 ppm macer8 ${ }^{\text {TM }}$ FJ for mash treatment and 20 ppm macer8 ${ }^{\text {TMF }} \mathrm{FJ}$ for juice clarification $+0.035 \%$ cramel (Em+Cr2).
5. clear apple juice produced by 250 ppm macer8${ }^{\text {TMF }} \mathrm{FJ}$ for mash treatment and 20 ppm macer8 ${ }^{\text {TMF }} \mathrm{FJ}$ for juice clarification $+0.02 \%$ cramel + 30 ppm apple essence (Em+Cr1+F).
6. clear apple juice produced by 250 ppm macer8TMFJ for mash treatment and 20 ppm macer8 ${ }^{\text {TM }} \mathrm{FJ}$ for juice clarification $+0.035 \%$ cramel+30 ppm apple essence (Em+Cr2+F).
7. clear apple juice produced by 300 ppm pectinase 444 L for mash treatment and 20 ppm pectinase 444 L for juice clarification $+0.035 \%$ cramel+30ppm apple essence (Ep+Cr2+F).

Clear seven drinks were analyzed for TSS, acidity (as citric acid \%), pH , clearance (absorbance at 660 nm ), reducing sugars \% and total sugars \% at zero-time and at one month intervals for a total of 5 -months storage at refrigerator temperature ( $4^{\circ} \mathrm{C}$ ). Sensory and microbiological evaluations were carried out at zero-time and at one month and half intervals, to the end of the storage period.

## Methods of analysis <br> Chemical analysis

Total titratable acidity, pH and reducing and total sugars were determined as described in the AOAC (1990).

## Physical anslysis

Total soluble solides ( ${ }^{\circ}$ Brix) were measured according to the AOAC (1990) by Abbe refractometer at $20^{\circ} \mathrm{C}$. And clearance was determined according to Staelehamatschek (1989) with little modifications (Mostafa, 2004). Apple juice was centrifuged at 4000 rpm for 25 min . The clearance of the supernatant was measured by a spectrophotometer at 660 nm .

## Sensory evaluation

Juice samples were sensory evaluated for colour, taste, aroma and appearance. Sensory assessments were carried out by ten semi-trained panelists on a 7-point hedonic scale from excellent, very good, good, satisfactory, poor, very poor, to extremely poor, which for analysis were scored from 7 to 1 (McBride and Richardson, 1983).

## Microbiological analysis

Microbiological quality of clear apple drinks were periodicaly examined for bacteria; mold and yeast. For total count of bacteria, trypton glucose extract agar was used. Counts of molds and yeasts were carried out by antibiotic agar method using standard methods agar. Antibacterial buffer (2\%) was added to sterile media befor use, for inhibition of bacterial growth. Dilutions up to 1: $10^{3}$ of tested treatments were cultivated. Counts of plates were taken after incubation of $24 \mathrm{hrs} / 37^{\circ} \mathrm{C}$ and $72 \mathrm{hrs} / 25^{\circ} \mathrm{C}$ for bacteria and (molds \& yeasts) respectively.

## Statistical anslysis

The analysis of variance (ANOVA) and LSD were performed by CoStat 6.311, Copyright(c) 1998-2005, CoHort Software, at probability $\geq 0.05$

## Fahem, Nancy I. et al.

(Snedecor and Cochran, 1967). Statistical analysis of sensory evaluations depended on ten replicates of degrees by the ten panelists.

## RESULTS AND DISCUSSION

## Preliminary experiments

Preliminary experiments were carried out to select the best treatments depending on juice yield, TSS, clearance and sensorial evaluations. Results are presented in Tables (1), (2), (3) and (4). Best treatments were selected for cold storage experiment.

Table (1) shows that juice yield, TSS and clearance values (absorbance at 660 nm ) of clarified apple juices increased significantly with increasing of enzyme concentration. Hence high concentration enzyme treatments will be considered in ongoing experiments.

From sensory assessments of clear apple drinks recorded in Table (2), the high concentration enzymatic treatments gained higher degrees of colour evaluation. It is obvious that the colour degree was affected by the clarity of the sample while the hazy control was refused. Also the taste of the higher enzymatic treatments were significantly better than other treatments especialy control. This could be due to the relative higher acidity caused by higher levels of enzyme treatments which balance the sweetness of the sugar and show good taste as the solubilization of cell wall polysacchrides effects various characteristcs of the juice obtained, like ${ }^{\circ} \mathrm{Brix}, \mathrm{pH} /$ acidity, contents and composition of phenolics, aroma and also the contents of solubilized polysaccharides (Voragen et al. 1992).

Treatment Macer at 250 ppm showed significantly the best aroma and other treatments were insignificant. Appearance quality of treatments followed the potential of enzymatic clarification and the higher enzymatic concentrations showed the best appearance. Josh et al.(2008) evaluated partially purified pectinase enzyme produced by Aspergillus niger for juice extraction and clarification of plum, peach, pear and apricot. The overall sensory evaluation of enzyme extracted juice using hedonic test showed a significant improvement in their clarity scores. The flavour of the extracted juice however remained unaffected by the addition of enzyme at al concentration.

Table (1): Juice yield, TSS and clearance of clarified apple juices produced using different pectinase concentrations.

In preliminary experiments, homogenization insignificantly increased crude juice yield from 78.3\% for non-homogenized mashs to 83.7\% for homogenized mashes (Table 3). Moreover, homogenization resulted in inefficient percipitation during the clarification process and loss more juice. Hence homogenization was ignored in the following production.

Table (3): Percent of juice yield from homogenized and nonhomogenized apple mashes.

| Treatment | Crude juice yield \% <br> (V/W) | Final clarified juice yield \% <br> (V/W) |
| :--- | :---: | :---: |
| Clear apple juice from non-homogenized <br> apple mash fermented by 250 ppm macer | 78.3 a | 63.0 a |
| Clear apple juice from homogenized apple <br> mash fermented by 250 ppm macer | 83.7 a | 63.7 a |

Mean in the same column with different superscripts are significantly different ( $\mathbf{p}<0.05$ ).
According to the data of preliminary sensory evaluation presented in Table (4), cramel treatments had significantly attractive colour and appearance, ranged between "very good" and "excellent" for $0.02 \%$ and $0.035 \%$ cramel in comparison with poor colour/satisfied appearance for control. Taste and aroma improved significantly by falvouring as flavoured treatments gained significantly very good characters and other treatments ranked good and satisfied.

The best treatments depending on juice yield, TSS, clearance and sensory evaluation were selected for further studies.

Physical and chemical characteristics of clear apple drinks during cold storage

Means of TSS of the treatments over the storage period ranged insignificantly ( $p>0.05$ ) between 13.75 and $13.92^{\circ}$ Brix for $\mathrm{Ep}+\mathrm{Cr} 2+\mathrm{F}$ and $\mathrm{Em}+\mathrm{Cr}+\mathrm{F}$, respectively as shown in Table (5) .

Brix of the treatments was influenced significantly by the storage period where its mean decreased significantly from $13.8^{\circ}$ at zero-time to $13.74^{\circ}$ by the fifth month of storage. Such reduction in the TSS could be due to the microbiological activity in the drinks (Ekoli and Ezenweke, 1990).

Enzymatic treatments exhibited insignificant acidity (Table 6). The acidity means of the treatments over the storage period reached the approximate value of $0.28 \%$, in comparison with the control which had significantly lower acidity of $0.199 \%$. Following the acidity mean of all treatments at each measurment, the mean increased significantly from $0.26 \%$ at zero-time to $0.273 \%$ at the fifth month. The increasing in acidity could be attributed to the microbial activity through the storage period (Okoli and Ezenweke, 1990).

Mean in the same column with different superscripts are significantly different ( $\mathbf{p}<0.05$ )
The pH means of the enzymatic treatments over the storage period were equal (3.55), while the control was significantly higher (3.73). The mean of pH of the treatments reduced significantly ( $\mathrm{p}<0.05$ ) with progressing of
the storage period from 3.59 at zero-time to 3.51 at the fifth month as shown in Table (7).

According to Schols et al.(1991), apple juices of straight pressing and pulp enzyming showed the same pH and total acidity of 3.4 and $0.29 \%$, respectively. Will et al. (2002) reported that the total titratable acidity (as citric acid) of apple juice was $0.45,0.44,0.46$ and $0.47 \%$ when treated the apple mash with pectinex Smash at 18, 40, 50 and $60^{\circ} \mathrm{C}$, respectively. Regarding that, $50^{\circ} \mathrm{C}$ is the optimum temperature of pectinases.

From the first glance at Table (8) which shows the clearance of clear apple drinks, it was found that, the treatments exhibited different significant degrees of clarification. The order of the absorbance means of the macer treatments over the five months storage period were; Em was the best clarified treatment which gave absorbance mean of 0.010, then Em+Cr1 and $\mathrm{Em}+\mathrm{Cr} 1+\mathrm{F}$ showed insignificant absorbance of 0.028 and 0.027 , respectively and $\mathrm{Em}+\mathrm{Cr} 2$ and $\mathrm{Em}+\mathrm{Cr} 2+\mathrm{F}$ showed insignificant absorbance of 0.042 and 0.04 , respectively. The results indicated that, the interference of cramel treatments with the absorbance at 660 nm . Ep+Cr2+F had the highest absorbance of enzymatic treatments (0.044) which indicated the efficiency of macer preparation for clarification of Anna apple than pectinase. The control treatment which was visually turbid had significantly the highest absorbance mean of 0.118 as it is not possible to remove the soluble pectin and obtain efficient clarification without the addtion of pectic enzymes or use alternative techniques (Araya-Farias et al. 2008) .

With progressing storage there was significant decreases of the absorbance mean of the treatments at each measurment from 0.055 at zerotime to 0.036 at the fifth month, this could due to fine particles that eventually settled out by centrifugation and the action of the gravity (Benitez and Lozano, 2007).

Table (9) shows that, at zero-time, reducing sugars contents were 1.9 to 2.09 \% for enzymatic treatments in comparison with $1.71 \%$ for control treatment. The means of the treatments over the five months were the same significance for macer treatments (1.62-1.63\%). Pectinase treatment showed significantly ( $p<0.05$ ) lower mean (1.45\%), then the control treatment showed significantly the least mean of $1.37 \%$. Contents of all treatments decreased significantly within the storage period. The means of reducing sugars of all treatments decreased significantly at each month, from zerotime to the fifth month, the corresponing values were 1.97 to $1.2 \%$, respectively.

Total sugar percent of clear apple drinks are presented in Table (10). At zero time, the total sugars of the enzymatic treatment ranged between 12.46$12.71 \%$ while the control treatment gave the lowest content of $12.06 \%$. Means of total sugar contents of each treatments over the fifth months storage period descended significantly from macer treatments which ranged between 12.46 to $12.53 \%$, to control and Ep+Cr2+F which had the same significance means of 12.12 and $12.05 \%$ respectively.
Over the five months storage period, the mean of the total sugar contents of all treatments decreased every month. It decreased significantly from 12.63 at the first month to $12.39 \%$ at the second month and again decreased significantly to 12.05 \% at the fifth month.

Resultes showed that enzymatic treatment affected significantly the acidity, pH , reducing sugars and the total sugar of clarified apple juice which are in agreement with results stated by many researchers, that, the solubilization of cell wall polysaccharides effects various characteristcs of the juices obtained like Brix, pH/acidity and also the content of solubilized polysaccharides. The amounts and types of polysaccharides released in the juice depend on the juice winning system, the conditions of enzyming, the enzyme preparations used and the method of clarification of the juice. It can be concluded that the enzyme preparation affects the intrinsic quality of the obtained juice which stated by Voragen et al. (1986). Also Voragen et al. (1992) found that the retentate of dialysed, conventionally clarified, straight pressed apple had a neutral sugar and uronide contents of $150 \mathrm{mg} / \mathrm{L}$ while for pulp enzyming juice this content was found to range from 1100 to $2510 \mathrm{mg} / \mathrm{L}$, depending on the enzyme preparation used. Moreover, enzyme treatments
increased the total amount of uronide content in clarified apple juice by a factor ranging between 4-15. It was found that in most juices between 50 and $90 \%$ of the uronides were dialysable (Voragen et al. 1992).

## Sensory evaluation of clear apple drinks stored at refrigerator

 temperature.Table (11) presents means of periodical sensory assessments for clear apple drinks carried out at one month and half intervals for five months at refrigerator temperature $\left(4^{\circ} \mathrm{C}\right)$. Results could be summarized in the following comment:

Table (11): Means of periodical sensory assessment of clear apple drinks stored for 5 months at refrigerator temperature $\left(4^{\circ} \mathrm{C}\right)$.

| Treatment | Character |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Colour | Taste | Aroma | Appearance |
| Control | 3.475 d | 4.08 c | 3.55 c | 3.375 c |
| Em | 4.45 c | 4.65 b | 4.28 b | 4.70 b |
| $\mathrm{Em}+\mathrm{Cr} 1$ | 5.33 b | 4.75 b | 4.43 b | 5.78 a |
| $\mathrm{Em}+\mathrm{Cr} 2$ | 6 a | 4.93 b | 4.48 b | 5.95 a |
| $\mathrm{Em}+\mathrm{Cr} 1+\mathrm{F}$ | 5.48 b | 6.15 a | 5.7 a | 5.90 a |
| $\mathrm{Em}+\mathrm{Cr} 2+\mathrm{F}$ | 6.15 a | 5.875 a | 5.6 a | 6.15 a |
| Ep+Cr2+F | 6.05 a | 5.65 a | 5.38 a | 6.15 a |

Mean in the same column with different superscripts are significantly different ( $\mathrm{p}<0.05$ ).

## Fahem, Nancy I. et al.

Cramel treatments of $0.035 \%$ were significantly ( $p<0.05$ ) the best colour treatments. Other treatments were significantly less attractive while the control was refused. Color of the drinks did not influenced by the storage time.

Flavoured treatments showed "very good" taste quality. Other unflavoured enzymatic treatments were only "good" taste while the control lowered significantly to "satisfied". In respect to the effect of the storage period, taste improved significantly after one month of storage which could be explained by the good combination of added flavour, natural apple taste and sugar that occured after a month of storage. After four and half months, taste quality decreased which could be attributed to weakness of added flavour.

Aroma of flavoured treatments was significantly better than other treatments. Other enzyme treatments had "satisfied" aroma while control was significantly poor. Aroma of all treatments decreased significantly with progressing of the storage period.

Cramel treatments showed very good appearance. The turbid control was refused. But appearance of the treatments did not influenced significantly by the storage time.

## Microbiological evaluation

At zero-time and untill the middle of the second month, the microbial load was under detectable levels (Tables 12 and 13), for the rest of the storage period, the log numbers of total bacterial count was less than one ( $<1$ ) and less than five $(<5)$ for molds \& yeasts.

Table (12): The log numbers of total bacterial count for clear apple drinks stored for 5 months at refrigerator temperature ( $4^{\circ} \mathrm{C}$ ).

| Treatment | Storage (month) |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | $\mathbf{0}$ | $\mathbf{1 . 5}$ | $\mathbf{3}$ | $\mathbf{4 . 5}$ |
| Control | ND | ND | $<1$ | $<1$ |
| Em | ND | ND | $<1$ | $<1$ |

| Ep+Cr2+F | ND | ND | $<5$ | $<5$ |

ND: not detected

## CONCLUSION

Clear apple juice was processed successfuly using commercial pectinases. Addition of cramel and flavour improved colour, taste, aroma and appearance of natural clarified drink. In respect to chemical chracteristics of the drink, the enzyme treatment increased acidity, reducing sugars and total sugars of the clarified apple drink, so it can be concluded that enzyme treatment affects the intrinsic quality of the obtained juice.

## Acknowledgement

The authors wish to thank Biocatalysts Limited, Wales, UK for its kind assistance by providing commercial enzymes used in this work.

* إنتاج عصير التفاح الرائق بإستخدام الإنزيمات البكتينية
 قسم الصناعات الغذائية، كلية الزراعة، جاعيا جامعة قـنـاة اللسويس، الإسمـاعيلية، مصر. جامعة هو هنهايم، ألمانيا*.
تم تصنيع عصير التفاح الرائق من صنف Anna (Malus spp.) المزروع فیى مصر خـلال مرحلتين، معالجـة لب التفاح بالإنزيمـات البكتينيـة ( تخمير اللب) ثم إجراء ترويق العصير و ذلك بإستخدام اللستحضر ات التجارية للإنزيمات البكتينية.
أضيف الكرامل بتركيزات مخنلفة و أسنس التفاح عند إعداد مشروب التفاح الرائق. خزنت مشروبات
النفاح لمدة خمسة أثهر على درجة حرارة الثلاجة، أجرى خلالهـا التحليالات الكيميائية و الطبيعية للمشروبات شهريا و كذلك التقييم الحسى و الميكروبيولوجى كل شهر ونصف حتى نهاية مدة التخزين.

الإنزيمات البكتينيـة التجاريـة وإضـافات النكهـة واللون التىى سـاعدت على تحسين الجودة الحسية للعصير من حيث اللون و النكهة و الرائحة و المظهر.
