## Prevalence of Cesarean Section Delivery and Associated Risk Factors

# Hanan M. Hathout<sup>1\*</sup>, Nehad B. A. Elsaid<sup>1</sup>, Hala M. Gabr<sup>1</sup>

<sup>1</sup>Public Health and Community Medicine Department, Menoufia University, Egypt. **Abstract:** 

Background: Cesarean section (CS) is a lifesaving procedure in the presence of maternal and fetal complications, but not indicated ones are associated with many adverse outcomes. Objectives: To study the prevalence and indications for cesarean section among the studied group also, studying the association between type of delivery and socio-demographic and obstetrics history of the studied group and comparing the maternal and fetal outcomes in relation to the type of delivery. Methodology: This retrospective study was conducted at Menoufia university hospitals. All records of delivered women at obstetric department during the period from 1 January 2019 to 31 December 2019 were collected. Patient affairs and statistics unit were reviewed for socio-demographic data, obstetric history, type of delivery, reasons of cesarean section, maternal and fetal outcome, and complications. Data were collected, analyzed, and tabulated using SPSS program. Results: Prevalence of cesarean sections was 45.9% and most of which were elective 59.8%. Associated significant risk factors were residence, educational and socioeconomic levels and working status. Post-partum hemorrhage was significantly high in CS delivery, while urinary incontinence and pelvic prolapse were more common with vaginal delivery. The main indication of CS in this study was previous CS 40.1%. Conclusion: Despite CS can be life saving for mother and baby in emergency indications, overuse of CS was associated with maternal and fetal complications. Efforts should be done to reduce the rate of elective CS through proper antenatal care counseling.

## Keywords: Cesarean section, Elective delivery, Prevalence, Risk factors

#### **Introduction:**

The cesarean section (CS) is a surgical procedure in which one or more incisions are made through a mother's abdominal layers and uterus to deliver one or more babies. A CS is supposed to be performed when a vaginal delivery would put the health of the mother or baby at risk. Accepted medical reasons for performing CS include failure of labor to progress, pelvic abnormalities, problems with the placenta, multiple gestation pregnancies, active herpes s simplex, irregularities of fetal heart rate, mal presentation of the fetus and any serious medical condition that requires emergency treatment.<sup>(1)</sup>

In the presence of maternal or fetal complications, cesarean delivery can effectively reduce maternal and perinatal mortality and morbidity however, there is an increasing proportion of babies are delivered by cesarean section when there is no medical obstetricc indication. The short-term adverse associations of cesarean delivery for the mother including infection, hemorrhage, visceral injury, and venous thromboembolism etc. <sup>(2)</sup>

Cesarean delivery is over utilized in middle to high income countries. The rate is as high as 25.9% in China, 32.3% in Australia, New Zealand and 45.9% in Brazil. Many of the cesarean deliveries in these countries were medically unjustifiable and thus unnecessary. In low-income countries, where over 60% of the world's births occur, the populationbased prevalence of CS is low for example, 3.0% in West Africa. This low prevalence may reflect poor availability or accessibility to comprehensive essential obstetric care services. <sup>(3)</sup>

Cesarean mode of delivery was overused in Egypt and the reasons due to financial incentive,

doctors' desire to have better control over their time, vagueness of medical protocols regarding indications for use of CS, limited opportunities for junior doctors to practice vaginal deliveries, shortage of pain relief drugs in public hospitals, and shortage of anesthesiologists who are trained in administration of epidural anesthesia which could be used to relieve pain in vaginal deliveries.<sup>(4)</sup> This paper aimed to study the prevalence and indications for cesarean section among the studied groups and the association between type of delivery and socio-demographic and obstetrics history of the studied groups. It also aimed to compare the maternal and fetal outcomes in relation to the type of delivery.

# Methods:

This retrospective analytical study was conducted at Menoufia university hospitals. All records of delivered women at the obstetric department during the period from 1 January 2019 to 31 December 2019 were collected. Patient Affairs and statistics unit were reviewed for socio-demographic data, obstetric history, type of delivery, reasons of cesarean section, maternal and fetal outcome and complications. Only completed records are included in this study 1712 records and 139 incomplete records were excluded.

**Ethical approval:** The Medical Ethics Committee at the Menoufia faculty of medicine approved the study protocol before starting the study thorough explanations of the study objectives through personal interviews with the chiefs of the patient affairs and statistics unit of Menoufia university hospitals.

**Tools:** Medical records had been reviewed with privacy to extract the following data:

- Socio-demographic data: Age, residence, education, working condition, socioeconomic level.
- History of previous pregnancies: Parity,
   Number of abortions, Previous CS,
   Previous fetal or maternal complications.
- History of current pregnancy: including frequency of antenatal care visits, fetal presentation, gestational age at delivery/weeks, fetal weight, fetal distress, associated medical problems of the mothers, type of delivery, type of cesarean section either elective or emergency.
- Indications of CS which may be cephalo-pelvic disproportion, placenta previa, oligohydramnios, hypertensive disorders of pregnancy. Mal-presentation, multiple pregnancies, intrauterine growth retardation (IUGR), post-term pregnancy, others.
- Neonatal outcome including Apgar score, IUFD, Neonatal Intensive Care Unit (NICU) admission.

 Maternal complications e.g.
 Postpartum Hemorrhage (PPH), blood transfusion, bladder injury, hysterectomy and septic wound.

• Length of hospital stay.

**Data management:** Data were collected, analyzed, and tabulated using SPSS (Version 22; SPSS Inc., Chicago, Illinois, USA). Two types of statistics were done.

Descriptive statistics in the form of number and percent for qualitative data, mean and standard deviation for quantitative data. Analytical statistics in the form of Chi-square test ( $\chi$ 2) was used to study association between two qualitative variablesandFischer exact testfor 2 x 2 tables when expected cell count of more than 25% of cases were less than five. Student's t- test was used for comparing means of quantitative parametric variables and Mann Whitney for nonparametric test quantitativevariables. P value <0.05 was considered statistically significant.

#### **Results:**

The prevalence of CS delivery among the studied groups was 45.9% (786 out of 1712). There was no significant difference between the study groups in relation to the age, but the prevalence of cesarean delivery was high in women living in urban in comparison to those in rural community (61.2% vs. 38.8%, P < 0.05). The rate of CS delivery also significantly increased with high educational level and in working woman and also with increasing the socioeconomic level (Table1). Prevalence of CS was high among primigravida in relation to multigravida (64.5% vs. 36.3%, P < 0.05), also prevalence of CS increased with increased number of previous abortions 60.2% of women

with history of repeated abortions more than 2 times delivered by CS P < 0.05), Most of the breech presentation was delivered by CS but this finding is not statistically significant. Also, there was significant difference in the fetal weight between two types of delivery.

No significant difference in the gestational age between vaginal and CS delivery groups (Table 2). There was no significant difference between type of delivery and fetal and maternal outcomes of the studied groups, but there was significant difference in the mean length of stay between CS delivery and vaginal delivery being higher for CS delivery (Table 3). The rate of paralytic ileus was significantly higher among CS delivery group, while pelvic organ prolapses, and urinary incontinence were the most common complications among women delivered by vaginal delivery (Table 4). The main indication that was contributed to CS in this study was previous CS (40.07%), followed cephalopelvic disproportion (17.6%), by abnormal presentations (8.9%), severe preeclampsia (5.34%), post term (5%), premature rupture of membranes (4.2%), placenta previa (3.56%), obstructed labour (3.31%), twins (2.67%) and intrauterine growth retardation (1.4%) (Table5).

## **Discussions:**

This study detected high cesarean sections rate for women delivered at Menoufia university hospitals during the year 2019; it was 45.9%, and this result is similar to Ayman et al.<sup>(5)</sup> who

http://efmj.journals.ekb.eg/

Egyptian Family Medicine Journal (EFMJ)

Vol .5(1), May 2021

found that the rate of cesarean sections was 41% in 2013, 45% in 2014, and 46% in 2015 in Tanta university hospitals. Also, the rate of Beni Suef general hospital was 32.6% and at Cairo university hospital and Al - Mattaria teaching hospital was 37.8% and 36.5% respectively, higher prevalence of CS in Alexandria was 70.4%.<sup>(6,7,8)</sup> The countries of the Arab world show a significant discrepancy in their CS rates, with some countries having significantly higher CS rates than others. For example, the rate of CS is more significant in Egypt than any other Arab country. The second highest rate is recorded in Jordan (28%) and the lowest was recorded in Yemen (5%). Such differences can be explained by each country's level of development. 15% Although rates exceeding are unnecessarily elevated, very low rates are also problematic as they may reflect lack of access to needed obstetric care in some low-income countries.<sup>(9)</sup>

In this study, high CS rate was detected for working women, and women with high socioeconomic levels, and this finding is supported by other studies as that of El zanaty et al.<sup>(10)</sup> In the present study, there was no significant association with CS rate and maternal age and this is similar to the finding of EDHS, 2014. In contrast to this finding, Alfred et al.<sup>(11)</sup> detect significant positive association with age. There is no satisfactory explanation for this linear association for age and CS rate. However, advanced maternal age may be and more significant number of previous CS, and previous obstetric complications or more medical disorders. In addition, over care for a precious baby may be more encountered for maternal age  $\geq$ 35 years and may be associated with non-medical CS.<sup>(12)</sup> No significant association was detected between the number of antenatal care visits and mode of delivery, this is against the finding of EDHS, as women who received four or more ANC visits were 2.5 times more likely to undergo a CS compared to women with no ANC visits. One hypothesis for this observed association is possibility that women that make more ANC visits more likely to have high-risk pregnancies and hence need to be delivered by CS.<sup>(10)</sup> In this study most of these CS deliveries

associated with pelvic rigidity, increased parity

were in primigravida, whereas vaginal delivery was common to multigravida. The lower likelihood of CS delivery of increasing parity could be explained by women with previous cesarean sections usually do not plan to get more than three offspring to avoid further CS delivery. <sup>(13)</sup>

There was a significant association with previous CS delivery and repeated ones, having previous CS was the strongest predictor of nonindicated CS. Obstetricians may repeat CS to avoid risk due to doubtful scar strength or absent information about the previous CS. In addition, Egyptian women with prior CS showed

http://efmj.journals.ekb.eg/

Egyptian Family Medicine Journal (EFMJ)

Vol .5(1), May 2021

favorable attitude to CS which surely reinforced this detectable high rate.<sup>(14)</sup>

In the current study, there was no significant difference in the mean Apgar score of CS and vaginal delivery groups. This finding is supported by Karamatollah et al.<sup>(15)</sup> On the other hand, Prior et al.<sup>(16)</sup> found that CS delivery was associated with low Apgar score and fetal distress in contrast to vaginal delivery which is associated with better outcome. An explanation for this finding is that vaginal delivery causes lung clearance from secretions and fluids with pressure on neonatal chest and support better respiration. On the other hand, drugs handled for anesthesia during cesarean sections can decrease uterine and placental circulation and causes fetal hypoxemia.

In our study there was significant difference in the mean length of stay between CS and vaginal mode of delivery as the mean length of stay for CS delivery longer than that of vaginal delivery. Length of hospital stay has been identified as an important quality indicator of obstetric care and efficiency of hospital performance. Extra length of hospital stay would be disadvantage for both the hospital and the patients by consuming hospital resources and providing extra-charge for the patients.<sup>(17).</sup> These figures were lower than the study of Keag et al. <sup>(18)</sup> that detect mean length of stays were  $2.9 \pm 1.1, 4.7 \pm 1.7$  for spontaneous, and cesarean delivery, respectively. In this study, the rate of NICU admission was 13.2% but there was no

significant difference in NICU admission rate for both study groups.

On the other hand, study of Fallah et al. <sup>(19)</sup> found that newborns delivered by CS were more likely to be admitted to NICU within 28 days of birth than those delivered vaginally and this finding after exclusion of multiple births, preterm births and small for gestational age. This may be due to hormonal and physiological changes of spontaneous delivery that helps lung maturation and and also catecholamine surge that occurs during labor likely plays an important role in both clearance of fetal lung fluid and glycemic control after birth. <sup>(20)</sup> On the other hand, planned vaginal delivery led to more meconium passage and low 1 min Apgar but less NICU admissions, oxygen resuscitation and jaundice. (21)

The most frequent complications to CS delivery of this study were postpartum hemorrhage, shock, wound dehiscence and sepsis, and visceral injury. This agrees with Keaget al<sup>.(18)</sup> who found that short-term risks of cesarean delivery include risk of infection, anesthetic and surgical complications including death and lower likelihood of breastfeeding. Surgical complications include hemorrhage requiring a transfusion or hysterectomy, bowel or bladder injury, postoperative ileus, amniotic fluid embolism, air embolism, thromboembolic disease and maternal death.

Primary indications for CS in this study were previous CS, followed by cephalopelvic

http://efmj.journals.ekb.eg/

Egyptian Family Medicine Journal (EFMJ)

Vol .5(1), May 2021

disproportion and abnormal presentations and this is supported by many other studies. <sup>(5,6,7,8)</sup> **Limitations:** Retrospective study liable to recall bias and depend on completeness and accuracy of the records and its design does not allow for causal interpretation of the associations studied. Also, we cannot generalize these results because we do not have data regarding the practices in private sectors which may favor much higher rate of CS delivery.

**Conclusions and Recommendations:** The high rate of CS delivery was recorded in this study and most of which were elective. CS delivery was associated with prolonged hospital stay and increased risk of postpartum hemorrhage. Efforts should be done to reduce the rate of elective CS through rationalization of CS delivery. Antenatal care counseling to educate women about the advantages of vaginal delivery and the adverse effects of medically not indicated CS.

**Fund:** The research was conducted with no fund.

**Conflict of Interest:** There was no conflict of interest.

# الملخص العربي معدل انتشار الولاده القيصريه وعوامل الخطوره المصاحبه لها

حنان محمد حتحوت – نهاد بدر عبد العاطي – هاله مروان جبر

**الخلفيه** : العملية القيصرية هي إجراء منقذ للحياة في وجود مضاعفات للام والجنين .وبالرغم من ذلك فإن العمليات غير المدعومة بمبررات قوية ترتبط بمضاعفات للأم والجنين .**الاهداف** :دراسة معدل انتشار الولاده القيصريه والعلاقة بين نوع الولادة والعوامل الاجتماعية وتاريخ الولادة وكذلك الأثار المرتبطة بنوع الولادة بين افراد العينه المدروسه.

المنهجية وطرق البحث :أجريت هذه الدراسة بأثر رجعي في مستشفيات جامعة المنوفية .تمت مراجعة جميع سجلات المرضى في قسم التوليد من خلال وحدة شئون المرضى والإحصاء خلال الفترة من 1 يناير 2019 إلى 31 ديسمبر 2019 ، لدر اسة البيانات الاجتماعية و الديمو غر افية وتاريخ التوليد ونوع الولادة و أسباب الولادة القيصرية ونتائج الولاده علي الأم و الجنين و المضاعفات. النتائج :كانت نسبة الولادة القيصرية في قسم التوليد بمستشفيات جامعة المنوفية 6.24 % خلال عام 2019 ومعظمها كانت اختيارية (%5.88) . العوامل المرتبطة بمعدلات أعلى للولادة القيصرية ذات الدلالة الإحصائية هي محل الإقامة، و المستويات التعليمية و الاجتماعية و الاقتصادية، وحالة العمل وكانت العوامل الهامة لتاريخ التوليد هي عدد الأولاد، وتوقيت الولادة، ووزن الجنين، ووجود تاريخ سابق للولادة القيصرية . لا يوجد فرق كبير في دخول وحدة العناية المركزة لحديثي الولادة وتقييم الحالة المحين، ووجود تاريخ سابق للولادة القيصرية . لا يوجد فرق كبير في دخول وحدة العناية المركزة لحديثي الولادة وتقييم الحالة ماصحية للأطفال حديثي الولادة القيصرية . لا يوجد فرق كبير في دخول وحدة العناية المركزة لحديثي الولادة وتقييم الحالة الصحية للأطفال حديثي الولادة القيصرية . لا يوجد فرق كبير في دخول وحدة العناية المركزة لحديثي الولادة وتقييم الحالة مقارنة بالولادة الطبيعية و الولادة القيصرية على التوالي . كان النزف التالي للولادة مرتفعاً بشكل ملحوظ في الولادات مقارنة بالولادة الطبيعية، في حين كان سلس البول و السقوط المهبلي أكثر شيوعاً مع الولادة الطبيعية، أكثر الأسباب شيو عا لولادات مقارنة بالولادة الطبيعية، في حين كان سلس البول و السقوط المهبلي أكثر شيوعاً مع الولادة الطبيعية، أكثر الأسباب شيو عا لولادات مقارنة بالولادة الطبيعية، في حين كان سلس البول و السقوط المهبلي أكثر شيوعاً مع الولادة الطبيعية، أكثر الأسباب شيو عا لولادات القيصرية في هذه الدراسة هو التاريخ السابق للولادة القيصرية (%0.01) . الاستناجات : على الرغم من أن الولادة القيصرية الطرنية قد تكون منقذة لحياة الأم والطفل، فإن از دياد معدلاتها يرتبط بحدوث بعض المصاعفات للأم والجنين و يجب بذل الجهود لخفض هذه المعدلات من خلال المراجعة الدقيقة لدواعي إجرائها والتدريب الكافي على الولادة الطبيعية وتو عية الحوامل بأهمية الولادة الطبيعية والأدان المراجعة الدقيقة
