

Knowledge and Attitude towards Smoking among Fayoum University Students

Naglaa A El Sherbiny*, Assem El Essawy**, Ekram M Abdel Khalek**

Abstract: Smoking is a behavioral cause of premature morbidity and mortality, resulting in approximately four million persons dying of smoking-related diseases annually worldwide. This study aims to investigate the extent of smoking habit, knowledge toward smoking among Fayoum University students. A cross sectional analytical study was conducted in Fayoum University during the academic year 2010. A total of 804 students were selected by using randomized multi-stage sampling using self-administered questionnaire for data collection. Data were analyzed using SPSS version 16. The respondents age ranged from 18 to 26 years $20.36 \pm (1.21)$ years. The males were 51% (n=410) and females were 49% (n=394). The prevalence of smoking among students was 13.4%. a large percentage of the smokers 82.4% used cigarettes while 8.3% smoked water pipe. Regarding knowledge about smoking related diseases, 97.3% of the students knew that smoking causes diseases; but only 5.6% of the sample had good/and satisfactory knowledge score about the causal role of tobacco in the development of specific diseases, and 66.7% of smoker students want to quit with a higher intention of for older group. In conclusion, smoking is prevalent among the university students and their knowledge about the harmful effects of smoking is generally superficial. Definite counseling programs are greatly needed to help students quit smoking.

Key words: *Smoking; university students; knowledge; attitudes*

INTRODUCTION

Smoking is the most important preventable cause of death, there are 4 million persons dying of smoking-related diseases annually. The annual mortality will exceed ten million during the 2020s. The prevalence of smoking in African countries ranged from 17% to 32%.⁽¹⁾ US Department of Health and Human Services reported that 48% of men and 7% of women in developing countries smoke. While in industrialized countries, 42% of men and 24% of women smoked.⁽²⁾ The harmful effects of cigarette smoking are destructive and widespread. Smoking affect, nearly every organ in the body and

*Public Health & Community Medicine Department Faculty of Medicine-Fayoum University

**Chest diseases Department Faculty of Medicine-Fayoum University

***Public Health& Community Medicine Department Faculty of Medicine-Assiut University

half of all long-term smokers die prematurely from smoking-related disease. For every person who dies from tobacco use, another 20 suffer; with at least one serious tobacco-related illness.⁽³⁾

According to CDC report; 80% of adult smokers began smoking before the age of 18 years and every day, nearly 3000 young people become regular smokers.⁽³⁾ If there is no action plan to stop initiate smokers, more than 5 million children will die prematurely because of future smoking as adolescents. Tobacco smoking among youth is a serious health issue in Egypt as it is reported that smoking prevalence among overall youth is 19.6%.⁽⁴⁾ University students are at high risk of smoking as they become exposed to smoking peers and face social, emotional and educational challenges.⁽⁵⁾ Knowledge about the dangers of smoking was a predictor of smoking behavior; and risk awareness alone seems to be insufficient to stop smoking.⁽⁶⁾ Smoking cessation is the most important,

cost-effective preventive intervention that can offer to smoker person.⁽⁷⁾ Helping smokers to stop smoking should be the goal of every health professional through motivational process.⁽⁸⁾ This process begins with counseling; a skill that requires the ability to evaluate smokers readiness to quit and to encourage them into effective action. Doctors should ask all patients about their smoking habits according to guidelines of smoking cessation state regardless of the reason for consultation and should offer them brief advice on smoking quitting.⁽⁹⁾

This study aims to investigate the extent of the smoking problem among Fayoum University students and to determine their knowledge about smoking related diseases and their intention towards quitting.

SUBJECTS AND METHODS

A cross sectional analytical study was conducted in Fayoum University which is located in Fayoum Governorate, Upper Egypt during the academic year 2010. The suggested prevalence of smoking among

Egyptian youth aged 15 to 24 years according to the Demographic Health Survey 2008 was 6.2%.⁽¹⁰⁾ The study population consisted of a sample of 804 male and female students out of total Fayoum University students of 25,000 which was randomly drawn from different faculties. Sample was selected by multistage random sample technique. The fundamental criteria for sample selection included: students aged 18–26 years. An attempt was made to include representative proportions of male/female and junior /senior students. A total of 850 questionnaires were distributed among different faculties in Fayoum University. Full participation (total= 804) with a respondent rate of 94.6% was obtained. The students completed a self-administered Arabic questionnaire consisting of 21 items. The first six questions were demographics questions. seven questions about smoking experience pattern of smoking, and age of initiation, and the last eight questions were about knowledge of smoking related diseases concerning various risk factors as well as willing to quit.

The questionnaires were administered and collected in the same setting.

This study was reviewed and approved by the Faculty of Medicine Research Ethical Committee, and a waiver of consent form was approved. We used an anonymous questionnaire with no private or sensitive information. Before distributing the questionnaire, the researcher informed the students about the objectives of the study, and the confidentiality of their information. All participants had the right not to participate in the study.

Data were analyzed using SPSS software version 16, simple descriptive analysis in the form of means and standard deviations were calculated for numerical data. Qualitative data were described using percent distribution and chi square test. Inferential statistic test was used to detect differences between categories, with a significant level of less than 0.05.

Scoring of the knowledge was done where we the correct answer was scored 1

and the false or don't know answers were scored 0. The knowledge score was computed by summing all correct responses. Categorization of the knowledge was done as follows:

- Poor knowledge was considered if < 50% of questions were answered correctly.
- Satisfactory knowledge was considered if from 50% to 75% of questions were answered correctly.
- Good knowledge was considered if > 75% of questions were answered correctly.

RESULTS

In the present study, from 804 participating students, male respondents were 51% (n=410) and females were 49% (n=394), the students age ranged from 18 to 26 years with a mean (\pm SD) of 20.36 (\pm 1.21) years. A 58.8% (n=470) of the students were from urban areas, while 41.2% (n=334) were in rural areas residency. The Applied sciences faculties represented 60.7% of the study sample (Faculty of Medicine, Faculty of

Engineering and Faculty of Sciences), whereas the theoretical faculties represented 39.8% (Faculty of Tourism, Faculty of Arts and Faculty of Social Work). The students were mainly in second, third and fourth grades 92.4% (n=743) as seen in Table 1.

The prevalence of smoking among Fayoum University students was 13.4% (26.3% in male and 0% in female). The majority of the smokers (82.4%) used cigarettes while 8.3% smoked water pipe. The average age of smoking initiation ranged from 12 to 22 years with a mean \pm SD of 17.73 \pm 1.99 years. The period of smoking ranging from 1 to 11 years with a mean \pm SD of 2.87 \pm 1.85 years. The numbers of cigarette smoking per day ranged from 1 to 40 with a mean \pm SD of 11.05 \pm 6.66 cigarettes and less than two thirds of smokers were moderate smokers as they consumed 10-20 cigarettes per day (Table 2).

A total of 439 (54.6%) of the students' families, one or more members were currently smoking

369 (84.1%) of which were cigarette smokers and, 182 (41.5%) of which were suffering from smoking related diseases such as chest disease (88.02%), heart diseases (8.2%), peptic ulcer (2.7%), osteoporosis (2.7%) and liver diseases (1.1%).

As regards knowledge about smoking related diseases, (n=782) (97.3%) of the study sample knew about harmful effect of smoking in developing different diseases such as cancer, chest and heart diseases. Regarding the source of information, the students took their knowledge about smoking hazards mainly from mass media (62.4%), followed by learning about smoking hazards from their study programs (19.7%). Also, health facilities and friends were considered as effective source of information (19.4% and 18.4%, respectively as shown in Table 4.

Figure 1 illustrates the score of knowledge about the causal role of tobacco in the development of specific diseases, only 1.7% of participants had good

knowledge, 3.9% their knowledge was satisfactory while the majority 94.4% had poor knowledge.

Good/satisfactory level of knowledge about smoking health hazards was relatively more among age group 18-20 years, urban residents, students in applied sciences faculties and tobacco smokers. These differences are statistically significant ($P < 0.05$). as shown in Table 5.

While 72 (66.7%) of smoker students intended to attempt quitting smoking, 36(33.3%) of them were not intended to do so even though they know its health hazards. The positive attitude of quitting is statistically significant among older age group (21-26) while no significant difference was found for the other studied variables (residence, faculty type and knowledge score.

DISCUSSION

Smoking and the use of other tobacco products has been linked to a wide range of detrimental health outcomes including cancer, cardiovascular disease and respiratory illness.

WHO (2008) ⁽¹¹⁾ estimates that 50% of smokers in Egypt will die of tobacco-related diseases. In addition, a growing number of Egyptian youth smoke Shisha (traditional water pipe), under the mistaken impression that it is less harmful.

The overall smoking prevalence of Egyptians aged 10-29 years is 26%. The majority of those who smoke are males in the age category 18-29.⁽¹²⁾ The results of our study showed a smoking prevalence of 26.3% of male university students, which is almost the same as the overall national level, but lower than the prevalence of current smokers in Ain Shams University (31.5%).⁽¹³⁾

The majority of the smokers (82.4%) used cigarettes while (8.3%) smoked water pipe (Shisha). In a study of tobacco prevalence among Health Sciences College students in Riyadh, 33% of males and 6% of females smoked cigarettes and 30% of males and 5.6% of females smoked Shisha⁽¹⁴⁾. The increasing trend of Shisha smoking observed in the last decade is accredited to the

misconceptions regarding its use, for instance that nicotine content is lower than that of cigarettes and that water filters out all the noxious chemicals.

In the present study, there was no female smokers which was in agreement with a study of 600 hostel residents of Alexandria University where 17.5% of males and 0% of females were current smokers.⁽¹⁵⁾ In a survey of 559 students University of Cairo aged 15–27 years, 22% were current smokers, compared with 1.7% of females who were current smokers.⁽¹⁶⁾ Female smoking is less in Upper Egypt because the culture prohibits female smoking and this is governed by the claimed male superiority present in this culture and supported by the social stigma associated with female smoking.

The mean age of smoking initiation \pm SD is 17.73 ± 1.99 years and 92.6% of students started smoking before age of twenty. The period of smoking ranging from 1 to 11 years with 73.1% smoked for 1-3 years and less than two thirds of smokers were moderate

smokers as they consumed 10-20 cigarettes per day. The previous findings are nearly similar to those found by Youssef et al.,(2002)⁽¹⁷⁾ who reported that the mean age of smoking initiation was 18.1 years. But Yorulmaza et al., (2002) ⁽¹⁸⁾ found that the age of smoking onset of Turkish adolescents was 13.02 ± 2.78 years, the average smoking rate of the smokers was 5.65 ± 5.89 cigarettes/ day and the mean duration of smoking was 3.07 ± 2.63 years.

Regarding knowledge about smoking related diseases our results revealed that 97.3% of respondents knew the effect of smoking in developing different diseases. However, the knowledge score about the causal role of tobacco in the development of specific diseases is poor in 94.4% of the students and the main source of their knowledge is the mass media (62.4%). This finding is below the mean knowledge score percentage of smoking among members of university students' unions in Ain Shams University was 79.4 ± 20.7 .⁽¹³⁾ In Riyadh,

around 86% of smokers were found to have more knowledge about the harm of tobacco use and their families and friends were the main sources of this knowledge.⁽¹⁴⁾

In our study, 66.7% of smoker students want to quit and this attitude is higher among older age group (21-26). This finding is similar to the result of public health research consortium that 67% of male and 76% of female (20-24) years old regular smokers) want to give up.⁽¹⁹⁾ In another study, Glantz and Jamieson.⁽²⁰⁾ found that the majority of young smokers report that they want to quit, and the prevalence of ex-smokers increases with age among 16-24 year olds. Abolfotouh reported that among 44 smokers students in Alexandria University Hostels, 90.1% wanted to reduce their smoking as a first step to quit.⁽¹⁵⁾

CONCLUSION AND RECOMMENDATIONS

This study concluded that smoking is prevalent among Fayoum University students. The knowledge of the harmful effects of smoking is generally poor.

- An intensive anti-smoking educational program aimed at changing behavior and attitude of tobacco smoking.
- Opening of smoking cessation clinic in the University hospital to help students in quitting with a motivational counseling sessions.
- Activation of policy and regulation to reduce youth access to tobacco products.
- Introducing teaching information about dangerous effect of smoking in the school and university curricula.
