### ABSTRACT

Yeast extract (100 and 200 ml/L) and GA<sub>3</sub> (20 and 40 ppm) were foliar sprayed on Thompson Seedless and Roumi Red grape cultivars. The treatments were done before flowering (2<sup>nd</sup> week of April) and at full bloom (1<sup>st</sup> week of May). Fruit set (%) and number of clusters/vine of both cultivars were increased significantly. In addition, yield was increased as a result of cluster weight, length and berries weight. Number of berries/cluster also improved significantly by yeast extract + GA<sub>3</sub> and yeast extract treatment alone for "Thompson Seedless" and "Roumi Red", respectively.

All treatments increased juice percentage of "Thompson Seedless" berries, however, juice content of "Roumi Red", soluble solids content (SSC), SSC/acid ratio and total sugars were increased while acidity decreased significantly for both cultivars. The combination of yeast extract at 100 ml/L and GA<sub>3</sub> at 40 ppm is recommended for improving yield and fruit quality of Thompson Seedless and Roumi Red grape cultivars.

### INTRODUCTION

Grapes (*Vitis vinifera* L.) are considered one of most popular and favorable fruits in the world. In Egypt, they occupy about 148406 fed. are cultivated with total production of 1078912 tons (Ministry of Agriculture 2001). Grapes ranked second after citrus. The main cultivar grown in Egypt is Thompson Seedless (Banati) followed by Roumi Red. The application of yeast extract to improve grapevine growth and cluster quality is of great importance. The various positive effects of applying yeast extract as a newly used biofertilizer were attributed to its content of different nutrients, higher percentage of proteins, larger amount of vitamin B and the natural plant growth regulator as cytokinin (Larson *et al.* 1962, Wareing and Phillips, 1973, Moor, 1979, Ferguson *et al.* 1987 and Mahmoud, 2001).

Ahmed *et al.*, (1997) and Abd El-Ghany *et al.*, (2001) reported that active dry yeast extract at 0.1 % improved yield and quality of "Roumi Red" berries. On "Thompson Seedless", El-Mogy *et al.*, (1998) found that yield, berry weight and size, bunch weight, SSC and SSC/acidity were increased significantly, while, acidity decreased with yeast extract application. Abd-El-Ghany *et al.*, (2001) also found an increment in cluster length and width but the data failed to show significant differences.

El-Khoreiby *et al.*, (1988 a, b) reported that application of GA<sub>4+7</sub> on Roumi Red grapevines greatly increased vines yield, cluster weight and size compared with the untreated ones. They also added that GA<sub>4+7</sub> at 5 ppm was more effective in increasing cluster compactness.

Concerning GA<sub>3</sub>, Surasak and Choopang (1988) pointed out that application of 25-100 ppm GA<sub>3</sub> increased berry size in both Cardinal and Loose Perlette cultivars. All GA<sub>3</sub> concentrations decreased SSC, SSC/TA and increased TA in Cardinal cultivar and decreased SSC, TA and SSC/TA in

Loose Perlette cultivar. Goday and Gustavo (1993) found that GA<sub>3</sub> application on "Muscat of Alexandria" decreased the number of berries per cluster, shot berries and increased SSC, however cluster weight was not effect.

Lu *et al.*, (1997) reported that GA<sub>3</sub> at 100, 200 and 300 ppm on "Muscadine" grape produced more than 20 % seedless berries and size of seedy berries was significantly increased.

The present work aims to investigate the response of Thompson Seedless and Roumi Red grape cultivars, to foliar spray with yeast extract and GA<sub>3</sub> solutions, each at two concentrations either alone or in combinations.

## MATERIALS AND METHODS

This study was carried out through 2001 and 2002 seasons on 15 years old "Thompson Seedless" and "Roumi Red" grape vines grown at the Experimental Station of the Faculty of Agriculture, Moshtohor, Qalubia Governorate.

Twenty-seven grapevines of each cultivar, at approximately the same vigor, were selected for this study. The vines were planted at 2 x 3 meters apart in clay loamy soil, cane trained (Thompson Seedless) or head trained (Roumi Red), and had the same number of eyes (60 for each vine) and subjected to the recommended vineyard management (Ministry of Agriculture).

The treatments, which applied in a complete randomized block design, were as follows: Control (water spray), Yeast extract at 100 ml/L., Yeast extract at 200 ml/L., GA<sub>3</sub> at 20 ppm., GA<sub>3</sub> at 40 ppm., Yeast extract at 100 ml/L.+ GA<sub>3</sub> at 20 ppm., Yeast extract at 200 ml/L.+GA<sub>3</sub> at 20 ppm., Yeast extract at 100 ml/L.+GA<sub>3</sub> at 40 ppm and Yeast extract at 200 ml/L.+GA<sub>3</sub> at 40 ppm.

Each treatment was replicated three times (one vine per each). Devoted vines for each treatment was sprayed twice during each season (the first one was before flowering (2<sup>nd</sup> week of April), while the second spray was at full bloom (1<sup>st</sup> week of May).

### Preparation of Yeast extract:

The dry pure yeast powder was activated by using sources of carbon and nitrogen with the ratio of 6:1 (Barnett *et al.*, 1990 and EL-Desouky *et al.*, 1998). This ratio is suitable to get the highest vegetative production of yeast (each ml yeast contained about 12000 of yeast cells). Then the media was frozen and thawed directly before usage. Tween- 20 was added as a spreading agent for all treatments.

The yeast extract used in the present study was analyzed for phytohormones, mineral elements" macro and micro", amino acids, total carbohydrates, reducing sugars as glucose, enzymes and Vitamins by Mahmoud (2001) as shown in Table (1) and Fig. (1).

### The following parameters were evaluated:

#### 1- Berry set percentage:

It was estimated by bagging ten flower clusters per vine using perforated paper bags after the second treatment.

Table (1): Chemical analysis of yeast extract.

Macro (g/100g dry weight)	Minerals		Amino acids (mg/100g dry weight)	Carbohydrates (mg/100g dry weight)	Enzymes (mg/100g dry weight)	Vitamins (mg/100g dry weight)
	Micro (ug/100g dry weight)					
Total N	7.23	Al	Arginine	Carbohydrates	Cytochrome oxidase	Vitamin B1
P <sub>2</sub> O <sub>5</sub>	51.68	Ba	Histidine	Glucose	Cytochrome peroxidase	Vitamin B2
K <sub>2</sub> O	34.39	Co	Isoleucine		catalase	Riboflavin
Na <sub>2</sub> O	0.35	Pb	Leucine			Nicotinic acid
MgO	5.78	Mn	Lysine			Panthenic acid
CaO	3.05	Sn	Methionine			Biotin
SO <sub>2</sub>	1.55	Zn	Phenylalanine			P- amino benzoic acid
SO <sub>3</sub>	0.49		Threonine			Vitamin B6
Cl	0.08		Tryptophan			Folic acid
FeO	0.92		Valine			Thiamin
NaCl	0.30		Glutamic acid			Pyridoxine
			Serine			Vitamin B12
			Aspartic acid			Inositol
			Cysteine			153 (ug/100g)
			Proline			283.13 (ug/100g)
			Tyrosine			

At the end of berry set stage, bags were removed and the dropped flowers and berries were counted. Percentage of berry set was calculated by dividing the number of developing berries by the total number of flowers and berries in the selected clusters.

$$\text{2- Seedless berry percentage} = \frac{\text{No. of seedless berries per cluster} \times 100}{\text{Total No. of berries per cluster}}$$

**3- Yield indicators:**

Clusters were collected at the 2<sup>nd</sup> week of June for Thompson Seedless and 3<sup>rd</sup> week of August for Roumi Red cultivar. The yield was expressed by the number of clusters per vine and by weight (Kg).

**4- Physical properties:**

Cluster weight (gm.), cluster length and width (cm.), number of berries per cluster, 100-berry weight, juice volume (cm<sup>3</sup>) per 100 berries and shot berries (%) in Roumi Red cv. only were recorded.

**5- Chemical properties:**

SSC (%), acidity (%), SSC / acid ratio, total sugars, reducing and non reducing sugar contents were determined according to A.O.A.C (1985).

**Statistical analysis:**

Data obtained during both seasons were subjected to analysis of variance according to the method described by Snedecor and Cochran (1980). Means were differentiated using Duncan's multiple testes (Duncan, 1955).

**RESULTS AND DISCUSSION**

**1- Berry set percentage:**

Data in Tables 2 and 3 revealed that spraying "Thompson Seedless" vines with yeast extract at 100 and 200 ml/L, GA<sub>3</sub> at 20 and 40 ppm either alone or in combinations increased berry set significantly over the control. The best results were obtained when the combinations of yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm was applied. Similarly, Loony (1974) enhanced berry set of Himrod and Chaunac grapes by GA<sub>3</sub> at 40 ppm.

**Table (2): Effect of yeast extract and GA<sub>3</sub> foliar sprays on Thompson Seedless\_ berry set (%), yield (Kg) / vine, and number of clusters / vine during 2001 and 2002 seasons.**

Treatments	Berries set (%)		Yield/vine (Kg.)		No. of clusters/vine

Means within each column have different letter (s) are significantly different using Duncan's multiple range test at the 5(%) level.

Application of yeast extract or GA<sub>3</sub> alone on "Roumi Red" reduced fruit set percentage in 2002 and 2003 seasons. However, all combinations of yeast extract and GA<sub>3</sub> increased fruit set (%). In this respect, Hifny *et al.*, (1980) found that GA<sub>3</sub> decreased Thompson Seedless fruit set. In contrast, El-Khoreiby *et al.*, (1988-a) using GA<sub>4+7</sub> at 10 ppm increased fruit set percentage in Roumi Red grape. The conflicting effect of GA<sub>3</sub> may be due to the concentration, time of application and / or growth habit. In addition, the response of both seedless (Thompson Seedless) and seeded (Roumi Red) grapes to GA<sub>3</sub> was different.

### 2- Seedless berry percentage:

Regarding percentage of seedless berries in Roumi Red grape, data in Table 3 indicated that, all treatments of yeast extract and GA<sub>3</sub> each alone or in combination significantly increased percentage of seedless berries. The increases ranged between 38 % with GA<sub>3</sub> at 20 ppm to 96 % with yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm compared with control in both seasons. Similarly, El-Khoreiby *et al.*, (1988-b) reported that GA<sub>4+7</sub> at 5 – 20ppm tended to decrease seed number/berry on Roumi Red grape. Lu *et al.*, (1997) reported that "Triumph" Muscadine grape sprayed with GA<sub>3</sub> at 100, 200 and 300 ppm produced more than 20 % seedless berries. Also, Omran (2000) found that soil drench of yeast extract application significantly decreased seed number per berry on Roumi Red grape.

### 3- Yield indicators:

As for the response of "Thompson Seedless" grape to yeast extract and GA<sub>3</sub> data in Table 2 illustrate that all treatments of yeast extract and GA<sub>3</sub> either alone or in combinations significantly increased the yield expressed as (Kg/vine). The highest yields were obtained from the combination of yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm (11.4 and 12.5 Kg/vine) compared with control (6.20 and 6.50 Kg/vine) in both seasons, respectively. These results are in agreement with El-Koreiby *et al.*, (1988-a) reported that spraying GA<sub>4+7</sub> or GA<sub>3</sub> increased the harvested yield. In addition, Ahmed *et al.*, (1997), El-Mogy *et al.*, (1998) and Kamelia *et al.*, (2000) indicated that application of yeast extract or soil drench increased the harvest yield. It is evident from data in Table (3) that yeast extract at 100 and 200 ml/L and GA<sub>3</sub> at 20 and 40 ppm

treatments, in the first season, increased significantly the yield (Kg/vine) over the control and other treatments. In the second season, all treatments of yeast extract and GA<sub>3</sub> either alone or combined together significantly increased the yield Kg/vine compared with control except the application of yeast extract at 200 ml/L + GA<sub>3</sub> at 20ppm and yeast extract at 100 ml/L + GA<sub>3</sub> at 40 ppm. The yeast extract at 200 ml/L achieved the maximum yield (6.98Kg/vine) in the first season and GA<sub>3</sub> at 40ppm achieved the maximum yield (7.65 Kg./vine) in the second season of Roumi Red grape.

Number of cluster per Thompson Seedless vine improved significantly when sprayed with yeast extract and GA<sub>3</sub>. Data in (Table 2) show that, in the first season, the highest values were obtained with yeast extract at 200 ml/L (17.77): In contrast, the lowest value (15.47) was obtained with GA<sub>3</sub> at 40 ppm. In the second season, all treatments of yeast extract and GA<sub>3</sub> significantly improved number of cluster/vine compared with control.

Concerning the response of Roumi Red grape to yeast extract and GA<sub>3</sub>, data in Table 3 show that, in the first season, no significant differences between the effect of all treatments and control on the number of cluster/vine. On the other hand all tested treatments of yeast extract, GA<sub>3</sub> and their combinations significantly increased the number of cluster/vine, in the second season. The highest result (16.0) was obtained when yeast extract at 200 ml/L combined GA<sub>3</sub> at 40 ppm compared with control (13.00): These results are in harmony with those of Ahmed *et al.*, (1997) and Omran, (2000) when applied yeast extract to Roumi Red grape.

#### 4- Physical properties:

Yeast extract, GA<sub>3</sub> and their combinations significantly improved cluster weight, cluster length and cluster width of Thompson Seedless grape Table (4). The highest results were obtained with yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm in both seasons. On the other hand, applications of the same treatments to Roumi Red grape show that yeast extract and GA<sub>3</sub> alone increased cluster weight in both seasons. In contrast, the combinations of yeast extract and GA<sub>3</sub> reduced significantly cluster weight compared with control in both seasons. Data also reveal that all treatments increased cluster length especially, yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm (30.60 and 32.00 cm) compared with check treatment (23.0 and 22.0 cm) in both seasons, respectively. Concerning, cluster width of Roumi Red grape, there was no response to yeast extract and GA<sub>3</sub>, each alone in both seasons, but the combinations of yeast extract and GA<sub>3</sub> reduced cluster width, specially yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm in both seasons Table (5). These results are in line with those obtained by El-Mogy *et al.*, (1998) on Thompson Seedless grapevine and Ahmed *et al.*, (1997), Omran, (2000) and Abd El-Ghany *et al.*, (2001) on Roumi Red grape vines.

As shown in Tables 4 and 5 all treatments of yeast extract and GA<sub>3</sub> either alone or combined together significantly increased number of berries per cluster, average weight 100 berries (except GA<sub>3</sub> at 20 ppm) and juice volumes of 100 berries in Thompson Seedless grape vines compared with control in both seasons.

Table (4): Effect of yeast extract and GA<sub>3</sub> foliar sprays on some physical properties of Thompson Seedless grapes during 2001 and 2002 seasons.

Means within each column have different letter (s) are significantly different using Duncan's multiple range test at the 5(%) level.

On the other hand, Roumi Red grape showed opposite response to yeast extract and GA<sub>3</sub> where berries number per cluster had significantly decreased with the applications of yeast extract or GA<sub>3</sub> alone but significant increased with combinations of yeast extract at 200 ml/L and GA<sub>3</sub> at 40 ppm in the first season or yeast extract at 100 or 200 ml/L + GA<sub>3</sub> at 40 ppm in the second season. The lowest numbers of berries / cluster (102.8 and 104.0) resulted from the applications of yeast extract at 100 ml/L. However, the same treatment resulted in the highest values of average weight 100 berries (438 and 456 gm) in both seasons, respectively. All treatments significantly reduced juiciness of berries compared with control in both seasons. On Thompson Seedless and Roumi Red grapevines the application of yeast extract and GA<sub>3</sub> either alone or in combinations, significantly reduced percentage of shot berries in both seasons compared with untreated control. The positive effect of yeast extract applications on physical characteristics of grape berries could be due to enhancing the formation and movement of natural hormones specially cytokinins and GA<sub>3</sub> and improving cell division and cell enlargement in meristematic tissues (Nijjar, 1985 and Shulman *et al.*, 1986). Vilsmeier and Amberger, (1988) added that the positive effect of yeast extract on physical characteristics of berries could be due to encouraging the uptake of various nutrients, or to active photosynthesis process through enhancing releasing carbon dioxide (Larson *et al.*, 1962). Moreover, yeast extract contains natural plant growth promoters specially IAA (Wareing and Phillips, 1973 and Moor 1979) and cytokinins (Ferguson *et al.*, 1987). These results were similar to those reported by Mohsen *et al.*, (1986) and Abd El-Ghany *et al.*, (2001) on Thompson Seedless grapes, and Ahamed *et al.*, (1997) and El-Mogy *et al.*, (1988) on Roumi Red grapes and Kamelia *et al.*, (2000) on King Ruby grapes.

Chemical characteristics of grape berries are illustrated in Tables 6 and 7, it was noticed that spraying the vine with the combinations of yeast extract and GA<sub>3</sub> induced a significant increase in soluble solids content (SSC) compared with control, on both Thompson Seedless and Roumi Red grapes in both seasons.

As for total acidity, both yeast extract and GA<sub>3</sub> or their combinations induced a reduction in total acidity of Thompson Seedless grape juice, while SSC/acid ratio as shown in Tables 6 and 7 was greatly affected by the experimental treatments. The marked increases in SSC/acid ratio was not only due to the increase in SSC %, but also due to the decrease acid contents in grape juice specially with the combinations of yeast extract at (100 or 200 ml/L) + GA<sub>3</sub> at 40 ppm, in both tested cultivars, in both seasons. No significant variances obtained between different treatments except yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm in the second season only.

It is evident from the data in Tables 6 and 7 that spraying the vine of both tested cultivars with yeast extract, GA<sub>3</sub> or their combination, increased total sugar contents in grape specially the combinations of yeast extract and GA<sub>3</sub> in the second season.

Table (6): Effect of yeast extract and GA<sub>3</sub> foliar sprays on some chemical properties of Thompson Seedless grapes during 2001 and 2002 seasons.

Means within each column have different letter (s) are significantly different using Duncan's multiple range test at the 5(%) level.

Similar results were obtained by Mohsen *et al.*, (1986) and El-Mogy *et al.*, (1998) on Thompson Seedless and all treatments showed a slight increase in reducing sugars except the treatment of yeast extract at 200 ml/L + GA<sub>3</sub> at 40 ppm in the first season and almost combined treatments in the second season which gave significant increase compared to control. Moreover, all treatments on Thompson Seedless grape gave insignificant effect in respect of non-reducing sugars in the first season, while no clear response in the second season was detected. On Roumi Red grapes all treatments significant by decreased reducing sugars, in contrast increased non-reducing sugars significantly in both seasons.

These results are in line with those obtained by Ahmed *et al.*, (1997), Omran, (2000) on Roumi Red grapes, Kamelia *et al.*, (2000) on King Ruby grape and Abd El-Ghany *et al.*, (2001) on Thompson Seedless.

Accordingly, it could be concluded that spraying Thompson Seedless and Roumi Red grapevines with the combinations of yeast extract at 100 ml/L + GA<sub>3</sub> at 40 ppm twice before flowering (2<sup>nd</sup> week of April) and at full bloom (1<sup>st</sup> week of May) is recommended to improving yield and fruit quality.

### استجابة صنفى العنب البناتى و الرومى الأحمر للرش بمستخلص الخميرة والجبرلين

- فاتن حسن محمود اسماعيل\* و محمد طه وهدان\*\* و احمد فتح الله الشيخ\*\*  
\* قسم النبات الزراعى - كلية الزراعة بمشهور - جامعة الزقازيق - فرع بنها.  
\*\* قسم البساتين - كلية الزراعة بالاسماعيلية - جامعة قناة السويس .

اجريت هذه التجربة على كرمات عنب طومسون سيدلس البناتى الأبيض مرياه بالطريقة القصبية و الرومى الأحمر مرياه بالطريقة الرأسية عمر ١٥ سنة مثمرة ومنزعة بمحطة التجارب بكلية الزراعة بمشهور بالقليوبية و ذلك لدراسة تأثير الرش بكل من مستخلص الخميرة بتركيز ١٠٠، ٢٠٠ مل/لتر وحمض الجبريليك بتركيز ٢٠ و ٤٠ جزء فى المليون و خليط منهما و ذلك مرتين الأولى قبل التزهير فى الأسبوع الثانى من ابريل (طول الفرخ ١٠ سم) و الثانية عند الإزهار الكامل فى الأسبوع الأول من مايو.

و قد أظهرت النتائج المتحصل عليها أن عقد الثمار و عدد العناقيد / كرمة و كذلك المحصول / كرمة قد زاد زيادة معنوية فى الموسمين فى كلا الصنفين مع معظم المعاملات. كذلك أظهرت النتائج وجود تحسن جوهري فى صفات العنقود (الوزن و الطول و العرض و عدد الحبات لكل عنقود) و وزن ١٠٠ حبة خصوصا فى المعاملات المشتركة ( ١٠٠ مل/لتر مستخلص خميرة + ٤٠ جزء فى المليون حمض الجبريليك ) مع صنف البناتى و فى معاملات الخميرة فقط مع صنف الرومى الأحمر بالنسبة لصفات وزن العنقود و عرض (اتساع العنقود) و وزن المائة حبة.

أما بالنسبة لعصير الحبات فقد أدت جميع المعاملات إلى زيادتها معنويا فى الصنف البناتى و انخفاضها معنويا فى صنف الرومى الأحمر و بالنسبة للمواد الصلبة الذائبة الكلية فقد زادت معنويا مع كل المعاملات فى الموسمين لكلا الصنفين كما كانت هناك زيادة فى نسبة المواد الصلبة الذائبة إلى الحموضة نتيجة لتأثير المعاملات المختلفة فى حين تناقصت النسبة المئوية للحموضة بسبب المعاملات كما أدت المعاملات المختلفة إلى زيادة السكريات الكلية فى عصير حبات الصنفين فى كلا الموسمين.

هذا و قد كانت أفضل المعاملات بصفة عامة هى الرش بمستخلص الخميرة ١٠٠ مل/لتر + حمض الجبريليك تركيز ٤٠ جزء فى المليون لكلا الصنفين. لذلك يمكن التوصية برش صنفى العنب البناتى و الرومى الأحمر مرتين الأولى قبل التزهير و الثانية عند الإزهار الكامل بمستخلص الخميرة بتركيز ١٠٠ مل/لتر + حمض الجبريليك بتركيز ٤٠ جزء فى المليون لزيادة الانتاجية وتحسين صفات جودة الثمار.
