## Abstarct

Let $M(x)$ be a function from $R^{k} \longrightarrow R$. Let $\theta_{n}$, $n=1,2, \ldots$ be vectors in $R^{k}$, $\theta_{l}$ being the value at which $M(x)$ achieves its unique minimum. Set $M(x)=M_{l}(x)$, for $n=1,2, \ldots$, set $M_{n}(x)=$ $M\left(x-\theta_{n}-\theta_{l}\right)$. Then $\theta_{n}$ is the unique minimum of $M_{n}(x)$, which is unknown and is to be estimated. In our case, we assume that $\theta_{n}$ moves in such a manner that $\theta_{n+1}=g_{n}\left(\theta_{n}\right)+v_{n}$ where $g_{n}\left(\theta_{n}\right)$ is general non-linear $k$-vector measurable function (known) defined for all $x \in R^{k}$ and $v_{n}$ is an unknown $k$-vector function (random or non-random) independent of $x$. Let $a_{n}, c_{n}, n=1,2, \ldots$ be two sequences of positive numbers. Let $x_{1}$ be an arbitrary random variable. Define for $n=1,2, \ldots, x_{n+1}=\stackrel{\star}{x}_{n}+a_{n}\left(\stackrel{\star}{y}_{2 n}-\stackrel{\star}{y}_{2 n-1}\right) / c_{n}$ where $\stackrel{*}{x}_{n}=g_{n}\left(x_{n}\right)$, and $\stackrel{\star}{y}_{2 n}, \stackrel{\star}{y}_{2 n-1}$ are random variables such that their expectations given $x_{1}, x_{2}, \ldots ., x_{n}$ are $\sum_{i=1}^{k} M_{n+1}\left(x_{n}+e_{i} c_{n}\right) e_{i}$ and $\sum_{i=1}^{k} M_{n+1}\left(x_{n}-e_{i} c_{n}\right) e_{i}$ respectively and their conditional variance are bounded by a constant $\sigma^{2}$ and they are conditionally independent. Under conditions similar to those used by Dupac (1966), we show that $\left\|x_{n}-\theta_{n}\right\| \longrightarrow 0$ with probability one.

## 1. INTRODUCTION

This paper is concerned with the dynamic Kiefer-Wolfowitz (KW) stochastic approximation procedure. This problem has been firstly studied by Dupac [2], [3]. He discussed in his papers the cases where the movement of the maximum can be expressed by a certain linear function of its present location and determinestic trend, i.e. he assume that

$$
\begin{equation*}
\theta_{n+1}=\left(1+\frac{1}{2}\right) \theta_{n}+v_{n} \tag{1.1}
\end{equation*}
$$

where $\theta_{n}$ is the unique maximum of the regression function $M_{n}(x)$. Uosaki, K. (l974) discussed the one-dimensional dynamic Robbins-Monto (rii) process. He considers the case where the movement of the root can be expressed by a specified non-linear function of its present location. Sorour (1978) geenralizes Woraki's iesult to the multidimensional dynamic (Rく). In this paper; we shall be concerned with the non-linear multidimensional dynamic systems. The convergence of the approximation to the moving minimum of a nonlinear regression function, with probability one, is proved. In sec. 4 we prove the convergence with probability one and in sec. '5, we show that under some regularity conditions on the noise, the process is asymtotoically normal.

## 2. DESCRIPTION OF THE PROCEDURE

Let $R^{k}$ be a real $k$-dimensional vector space. If $x$ and $y$ are two vectors in $R^{k}$ we denote their-inner product by $(x, y)$ and their nroms by $\|x\|$ and $\|y\|$ respectively. Let $M_{n}(x)$ be a (unknown)
function from $R^{k} \longrightarrow R$. Assume that $\theta_{n}$ is the unique minimum of $M_{n}(x)$. Our goal is to estimate $\theta_{n}$. In our case we assume that $\theta_{n}$ moves in a manner that

$$
\begin{equation*}
\theta_{n+1}=g_{n}\left(\theta_{n}\right)+v_{n} \tag{2.1}
\end{equation*}
$$

where $g_{n}(x)$ is in general a nonlinear measurable function (known) from $R^{k} \longrightarrow R^{k}$ and $v_{n}$ is unknown $k$ vector (non-random). Let $a_{n}, n=1,2, \ldots$ be positive numbers. Let $X_{1}$ be an arbitrary random variable define for $n \doteq 1,2, \ldots$.

$$
\begin{equation*}
X_{n+1}=\stackrel{\star}{X}_{n}-a_{n} F_{n} \tag{2.2}
\end{equation*}
$$

where

$$
\begin{align*}
& \stackrel{\star}{\mathrm{X}}_{\mathrm{n} 1}=\mathrm{g}_{\mathrm{n}}\left(\mathrm{X}_{\mathrm{n}}\right) ; \\
& \mathrm{F}_{\mathrm{n} 1}=\overline{\mathrm{D}}_{\mathrm{n}}+\mathrm{d}_{\mathrm{n}} \tag{2.3}
\end{align*}
$$

and the ith compenent of $\bar{D}_{n}$ is given by

$$
\bar{D}_{n}^{i}=\left[M_{n+1}\left(x_{n}+e_{i} c_{n}\right)-M_{n+1}\left(x_{n}-e_{i} c_{n}\right)\right] / 2 c_{n}
$$

where $e_{i}$ is the ith column in the identity matrix and $c_{n}$ is a positive sequence of real numbers. Let ${ }_{F}{ }_{n}$ be the $\sigma-f i e l d$ generated by $X_{1}, x_{2}, \ldots, X_{n}$. For $x$ a random vector in $R^{k}$ let $E_{n}(x)$ and $\operatorname{Var}_{n}(x)$ denote the conditional expectation and the conditional variance of $x$ with respect to $\mathfrak{F r}_{n}$ respectively. Let

$$
\begin{equation*}
E_{n}\left(d_{n}\right)=0 \tag{2.4}
\end{equation*}
$$

and for constant $k_{1}$ let

$$
\begin{equation*}
E_{n}\left(\left\|d_{n}\right\|^{2}\right) \leq k_{1} c_{n}^{-2} \tag{2.5}
\end{equation*}
$$

Let $D_{n}(x)$ denotes the vector of the partial derivatives of $M_{n}(x)$ Then

$$
D_{n}^{i}(x)=\frac{\partial M_{n}(x)}{\partial x^{i}}
$$

Assume that

$$
\begin{equation*}
\left\|D_{n}-D_{n+1}\left(\stackrel{\star}{x}_{n}\right)\right\| \leq k_{2} c_{n} \tag{2.6}
\end{equation*}
$$

In what follows $(Q, \not \approx, P)$ will be a probability space, relations and convergence of random variables, vectors and matrices will be meant with probability one. The indicator function of set $A$ will be denoted $x^{A}=R^{k \times k}$ is the space of all real $k \times k$ natrices. The unit matrix in $R^{k \times k}$ is denoted by $I$ and $\|\cdot\|$ is the Euclidean norm. With $h_{n}$ a sequence of numbers let $O\left(h_{n}\right)$, $O\left(h_{n}\right)$ denote sequerices $g_{n}$ and $G_{n}$, say of elements in one of the sets $R$, $R^{k}$ such that $h_{n}^{-1} g_{n} \longrightarrow 0,\left\|h_{n_{1}^{-1}} G_{n}\right\| \leq f$ for $f \in R$.

Remark $=$ Let $Y_{n}(i, 1), Y_{n}(i, 2)$ be two random variables such

$$
\begin{aligned}
& E_{n}\left(Y_{n}(i, 1)\right)=M_{n+1}\left(\stackrel{\star}{X}_{n}+e_{i} c_{n}\right) \\
& E_{n_{1}}\left(Y_{n}(i, 2)\right)=M_{n+1}\left(\stackrel{\star}{X}_{n}-e_{i} c_{n}\right)
\end{aligned}
$$

Then $F_{n}=\left[Y_{n}(i, 1)-Y_{n}(i, 2)\right] / 2 c_{n}$, and $Y_{n}(i, 1)$ and $Y_{n}(i, 2)$ are conditionally independent. If $\operatorname{Var}_{n}\left(Y_{n}(i, l)\right)$ and $\operatorname{Var}\left(X_{n}(i, 2)\right)$ are bounded. Then (2.5) holed. Also let $H_{n}(x)$ be the Hessian of $M_{n}(x)$ i.e.

$$
\begin{aligned}
& H_{n}^{i j}(x)=\frac{\partial^{2} M_{n}(x)}{\partial x^{i} \partial x^{j}} \\
& \text { If } \sup _{x}\left\{\left\|H_{n}(x)\right\|<\infty\right\} \text { for } n=1,2, \ldots \text { Then (2.6) holds. }
\end{aligned}
$$

## 3. CONSITIONS

$$
\text { Conditions on the regression function } M_{n}(x)
$$

$M 1$ : There existy two numbers $A$ and $B$ such that

$$
\left\|D_{n}(x)\right\| \leq A\left\|x-\theta_{n}\right\|+B
$$

M2 : For all $\delta>0$, we have

$$
\left.\operatorname{if~}_{n \in N} \quad \inf _{n} \quad \delta\left\|x-\theta_{n}\right\|<\delta^{-1}<x-\theta_{n}, D_{n}(x)\right\rangle>0
$$

Conditions on the sequences $a_{n}$ and $c_{n}$
Al: $\quad \sum_{n=1}^{\infty} a_{n} c_{n}<\infty ; \quad \sum_{n=1}^{\infty} a_{n}=\infty, \quad \sum a_{n}^{2}<\infty, \quad \sum_{n=1}^{\infty} a_{n}^{2} c_{n}^{-2}<\infty$ Conditions on the functions $g_{n}(x)$ and $v_{n}$
Gl : There exists a sequence of positive number $\gamma_{n}$ independent of $x$ and $y$ such that

$$
\left\|g_{n}(x)-g_{n}(x)\right\| \leq \gamma_{n}\|x-y\| \quad \text { for all } x, y \in R^{k}
$$

G2 : $\sum_{n=1}^{\infty}\left(\gamma_{n}^{2}-1\right)^{+}<\infty ;$ where $z^{+}$means $(x+|z|) / 2$
G3 : $\underset{n \longrightarrow \infty}{\lim } g_{n}(x)-g_{n}(y)-v_{n} \quad$ exists for all $\|x-y\|<\infty$ G4 : $\sum_{n=1}^{\infty}\left\|v_{n}\right\|<\infty$.

## 4. ASYMPTOTIC CONVERGENCE

Theorem 4.l. If the conditions Ml, M2, Al, Gl-G4 hold. Then

$$
\lim _{n \longrightarrow \infty}\left\|x_{n}-\theta_{n}\right\|=0
$$

Proof:- From (2.1) and (2.2) we have

$$
x_{n+1}-\theta_{n+1}=g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)-v_{n}-a_{n} F_{n}
$$

Thus

$$
\begin{aligned}
\left\|x_{n+1}-\theta_{n+1}\right\|^{2}= & \left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)-v_{n}\right\|^{2}-2 a_{n}\left\langle g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right. \\
& \left.-v_{n}, F_{n}\right\rangle+a_{n}^{2}\left\|F_{n}\right\|^{2} \\
= & \left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right\|^{2}-2\left\langle g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right), v_{n}\right\rangle+ \\
& +\|v\|^{2}-2 a_{n}\left\langle\stackrel{\alpha}{x}_{n}-\theta_{n+1}, F_{n}\right\rangle+a_{n}^{2}\left\|F_{n}\right\|^{2}
\end{aligned}
$$

Using (2.4) we obtain

$$
\begin{align*}
& E_{n}\left(\left\|x_{n+1}-\theta_{n+1}\right\|^{2}\right)=\left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right\|^{2}-2\left\langle g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right), v_{n}\right\rangle \\
& +\left\|\mathrm{v}_{\mathrm{n} 1}\right\|^{2}-2 a_{\mathrm{n}}\left\langle\stackrel{*}{\mathrm{x}}_{\mathrm{n} 1}^{*}-\theta_{\mathrm{n}+1} ; \overline{\mathrm{D}}_{\mathrm{n}}\right\rangle+\mathrm{a}_{\mathrm{n}}^{2} \mathrm{E}_{\mathrm{n}}\left(\left\|\mathrm{~F}_{\mathrm{n}}\right\|^{2}\right) \\
& \leq\left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right\|^{2}-2 a_{n}\left\langle\stackrel{\star}{x}_{n}-\theta_{n+1} ; \bar{D}_{n+1}\left(\stackrel{\star}{x}_{n}\right)\right\rangle \\
& +O\left(\left\|v_{n}\right\|\left\|g_{n_{1}}\left(x_{n_{1}}\right)-g_{n_{1}}\left(\theta_{n}\right)\right\|\right)+O\left(\left\|v_{n}\right\|^{2}\right. \\
& +0\left(a_{n}\left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)-v_{n}\right\|\left\|\bar{D}_{n}-D_{n+1}\left(\stackrel{*}{x}_{n}\right)\right\|^{2}\right) \\
& +0\left(a_{n}^{2}\left\|D_{n+1}\left(\stackrel{\star}{x}_{n}\right)\right\|^{2}\right)+0\left(a_{n}^{2}\left\|\bar{D}_{n}-D_{n+1}\left(\stackrel{\star}{x}_{n}\right)\right\|^{2}\right) \\
& +0\left(a_{n}^{2}\left\|E_{n}\left(d_{n}^{2}\right)\right\|\right) \tag{4.1}
\end{align*}
$$

By (2.5), 92.6 ) and $M l$ and using the identity $\|x\| \leq\|x\|^{2}+1$, we obtain

$$
\begin{align*}
E_{n}\left(\left\|x_{n+1}-\theta_{n+1}\right\|^{2}\right)= & \left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right\|^{2}-\left(1+0\left\|v_{n}\right\|\right)+0\left(a_{n} c_{n}\right) \\
& \left.+0\left(a_{n}^{2}\right)\right)-2 a_{n}\left\langle\stackrel{*}{x}_{n}-\theta_{n+1} ; D_{n+1}\left(\stackrel{*}{x}_{n}\right)\right\rangle \\
& +0\left(\left\|v_{n}\right\|+\left\|v_{n}\right\|^{2}+a_{n} c_{n}+\left\|v_{n}\right\| a_{n} c_{n}+a_{n}^{2}\right) \\
= & \left\|g_{n}\left(x_{n}\right)-g_{n}\left(\theta_{n}\right)\right\|^{2}\left(1+\mu_{n}\right) \\
& -2 a_{n}\left\langle\stackrel{*}{x}_{n}-\theta_{n+1} ; D_{n+1}\left(\stackrel{\star}{x}_{n}\right)\right\rangle+\delta_{n} \quad(4.2) \tag{4.2}
\end{align*}
$$

where

$$
\begin{aligned}
& \mu_{n}=0\left(\left\|v_{n}\right\|+a_{n} c_{n}+a_{n}^{2}\right) \\
& \delta_{n}=0\left(\mu_{n}+a_{n}^{2} c_{n}^{-2}\right)
\end{aligned}
$$

From Al and G4 it follows that

$$
\begin{equation*}
\sum_{n=1}^{\infty} \mu_{n}<\infty \quad \text { and } \quad \sum_{n=1}^{\infty} \delta_{n}<\infty \tag{4.3}
\end{equation*}
$$

Using Gl, (4.2) can be written as

$$
\left.\begin{array}{rl}
E_{n}\left(\left\|x_{n+1}-\theta_{n+1}\right\|^{2}\right) \leq & \left\|x_{n}-\theta_{n}\right\|^{2}-\left(1+\mu_{n}+\left(\gamma_{n}^{2}-1\right.\right.
\end{array}\right)
$$

From M2, G2, (4.3) and (4.4), it follows from Theorem 1 Robbins and siegmund [8] that

$$
\underset{\mathrm{n} \longrightarrow \infty}{\lim }\left\|\mathrm{x}_{\mathrm{n}}-\theta_{\mathrm{n}}\right\| \text { exists and finite }
$$

and

$$
\begin{equation*}
\sum_{n=1}^{\infty} a_{n}\left\langle\stackrel{\star}{x}_{n}-\theta_{n+1} ; D_{n+1}\left(\stackrel{*}{x}_{n}\right)\right\rangle<\infty . \tag{4.5}
\end{equation*}
$$

Using M2, Al and G3 obtain that

$$
\lim _{n \rightarrow \infty}\left\|x_{n}-\theta_{n}\right\|=0, \text { which completes the proof of theorem. }
$$

## 5. ASYMPTOTIC NORMALITY OF THE PROCEDURE

Theorem 5.1. L.et $A ; P \in R^{k \times k}$, $A$ positive definite, $P$ orthogonal,

$$
\begin{align*}
& P^{\prime} A P=\wedge \text { diagonal, } \lambda=\min \wedge(i j), 0<\beta<2 \lambda a, \\
& a_{n}=a n^{-1}, c_{n}=n^{-\gamma}, \gamma=\frac{1}{2}(1-\beta) ;  \tag{5.1}\\
& X_{n}-\theta_{n} \longrightarrow 0 \quad C>E_{n}\left(d_{n} d_{n}^{\prime}\right)-\Sigma \| \rightarrow 0 \\
& n^{-1} \sum_{j=1}^{n} \alpha_{j, r}^{2} \longrightarrow 0 \text { for every } r>0 \text { with } \\
& o_{j, r}^{2}=E_{x}\left\{\left\|d_{j}\right\|^{2} \geq r j^{\alpha}\right\}\left\|d_{j}\right\|^{2} \text { and }
\end{align*}
$$

let for $X_{n}$ in a neighborhoud of $\theta_{n}$

$$
\begin{equation*}
\left\|\bar{D}_{n}-A\left(x_{n}-\theta_{n+1}\right)-n^{-\beta / 2} m\right\| \leq 0(1)\left[n^{-\beta / 2}+\left\|\dot{x}_{n}-\theta_{n+1}\right\|\right] \tag{5.2}
\end{equation*}
$$

$$
\begin{equation*}
\left\|g_{n}(x)-g_{n}\left(\theta_{n}\right)-\left(x_{n}-\theta_{n}\right)\right\| \leq 0(1)\left[n^{-\beta / 2}+n^{-1}\left\|x_{n}-\theta_{n}\right\|\right] \tag{5.3}
\end{equation*}
$$

Then the asymptotic distribution of $n^{\beta / 2}\left(x_{n}-\theta_{n}\right)$ is normal with mean $-a(a A-(\beta / 2) I)^{-1} m$ and covariance matrix PMP' with $M^{(i j)}=a^{2} c^{-2}\left[P^{\prime} \Sigma P\right]^{(i j)} /\left(a \wedge^{(i j)}+a \wedge^{(i j)}-\beta\right)$

Proof : From (2.1) (2.2) and (2.3) we have

$$
\begin{equation*}
x_{n+1}-\theta_{n+1}=\stackrel{x}{x}_{n}-\theta_{n+1}-a n^{-1} D_{n}-a n^{-1} d_{n} \tag{5.4}
\end{equation*}
$$

From (2.5) it follows that

$$
\bar{D}_{n}=A_{n}\left(\stackrel{\star}{X}_{n}-\theta_{n+1}\right) n^{-\beta / 2} m_{n}
$$

with $A_{n}, m_{n}$ are $\mathscr{F}_{n}$-measurable and $A_{n} \longrightarrow A, \quad m_{n} \longrightarrow \quad m$ uniformally. Thus (5.4) can be written as
$x_{n+1}-\theta_{n+1}=\left(\stackrel{\star}{x}_{n}-\theta_{n+1}\right)\left(I-a n^{-1} A_{n}\right)-a n^{-1} n^{-\beta / 2}{ }_{n}$
$-a n^{-1} d_{n}$
Also it follows from (5.3) that

$$
\begin{equation*}
\stackrel{*}{x}_{n}-\theta_{n+1}=a_{n}\left(x_{n}-\theta_{n}\right)+n^{-\beta / 2} g_{n} \tag{5.6}
\end{equation*}
$$

where

$$
\begin{aligned}
& \mathrm{G}_{\mathrm{n}} \longrightarrow \mathrm{I} \\
& \mathrm{~g}_{\mathrm{n}} \longrightarrow 0
\end{aligned}
$$

uniformally, $\left\|G_{n}-I\right\|=0\left(n^{-1}\right)$.
Substituting (5.6) in (5.5) we get

$$
\begin{align*}
x_{n+1}-\theta_{n+1}= & \left(I-a n^{-1}\left(A_{n}+0(1)\right)\left(x_{n}-\theta_{n}\right)-\right. \\
& a n^{-1} n^{-\beta / 2}\left(m_{n}+0(1)\right)-a n^{-1} d_{n} \tag{5.7}
\end{align*}
$$

From (5.7) and Theorem (2.2) Fabian [5], giving the desired result.
