ABSTRACT

Background: Achondroplasia is the most common genetic skeletal dysplasia. It is characterized by a rhizomelic form of dwarfism, exaggerated lumbar lordosis, a prominent forehead and a low nasal bridge. The trunk is generally of near normal length. The incidence of achondroplasia is approximately 1 in 25000 people.

Objectives: In the present systematic review, we have aimed to synthesize evidence from the published literature about the safety and efficacy of limb lengthening in patients with achondroplasia. Also, we have aimed to assess which age is preferred to start the lengthening and effect of early management on natural growth and psychiatric health.

Methods: An electronic search was conducted from the inception till September 2018 in Medline via PubMed. Data entry and processing were carried out using a standardized Excel sheet and reviewers extracted the data from the included studies. We performed all statistical analyses using Review Manager (RevMan) 5.3 for windows.

Results: In the present study, 17 studies were included in the present systematic review and meta-analysis. In terms of gained length of femur, the overall effect estimate showed that limb lengthening procedure achieved a mean increase in femur length by 11.9 (95% CI 9.39 – 14.43) cm. In addition, the overall effect estimate showed that limb lengthening procedure achieved a healing index of femur 30.46 (95% CI 24.326 – 36.59) days/cm. Similarly, the overall effect estimate showed that limb lengthening procedure achieved a mean increase in tibia length by 9.5 (95% CI 8.169 – 10.927) cm. The overall effect estimate showed that limb lengthening procedure achieved a healing index of tibia of 32.09 (95% CI 18.65 – 25.52) days/cm

Conclusion: It could be concluded that limb lengthening is a reliable procedure with a relatively low complication rate in increasing the length of femur and tibia in patients with achondroplasia.

Keywords: Achondroplasia, Meta-analysis.

INTRODUCTION

Skeletal dysplasias are a group of genetic disorders that affect the size and shape of the limbs, trunk and skull, typically resulting in short stature ⁽¹⁾. On the basis of data from seven population-based birth defect-monitoring programs in the United States, the estimated prevalence of achondroplasia ranges from 0.36 to 0.60 per 10,000 live birth ⁽²⁾. Achondroplasia creates an external appearance of disproportionate short stature in which extremities are too short relative to the trunk and head, due to inadequate enchondral ossification in the long bones, with an adult height that is below the third percentile ⁽³⁾. In addition to the discomfiting cosmetic appearance, achondroplasia often results in lumbar (lordosis) and spinal stenosis later in life, which may require surgery to correct ⁽¹⁾.

Less commonly, achondroplasia may lead to neurological complications, craniofacial abnormalities, sleep-disordered breathing, thoracolumbar kyphosis, angular deformities of the knee and leg, otitis media, deafness, speech delay, weight gain and obesity ⁽⁴⁾.

Among the various surgical options that can be offered to those affected from achondroplasia, limb lengthening was proposed in order to increase height at maturity and restore normal body proportions in affected individuals ⁽⁵⁾. The fundamental research

conducted by Ilizarov led to a method allowing bilateral lengthening with acceptable risks ⁽⁶⁾.

Lengthening of the arms and legs of individuals with achondroplasia can potentially result in height gains of up to 30 cm and may improve limb function ⁽⁷⁾. On the other hand, limb lengthening was reported to be associated with high incidence of serious complications. There is a growing body of evidence that lengthening is commonly associated with infection, pain, swelling of the limb, neurovascular complications, contractures of the soft tissues, subluxation and dislocation of adjacent joint, bone-related problems at the lengthened site and psychological problems ⁽⁸⁾.

Previous study by **Donaldson et al.** ⁽⁹⁾, on ten achondroplastic children underwent limb lengthening, reported an average total length gain of 20.5 cm, with a high rate of complications. Another report by **Kim et al.** ⁽¹⁰⁾ assessed whether patients were satisfied with leg lengthening using the AAOS lower limb, SF-36, and Rosenberg self-esteem scores. The minimum follow up was 4.5 years. They concluded that even with numerous complications, serial limb lengthening is a good option in terms of improvement in quality of life scores.

The aim of the current study was to synthesize evidence from the published literature about the safety and efficacy of limb lengthening in patients with

achondroplasia. Also, we have aimed to assess which age is preferred to start the lengthening and effect of early management on natural growth and psychiatric health.

MATERIALS AND METHODS

We performed this systematic review and meta-analysis in accordance to the recommendations of the

Meta-analyses of Observational Studies in Epidemiology (MOOSE) statement. MOOSE is a reporting checklist for Authors, Editors, and Reviewers of Meta-analyses of Observational Studies. According to International committee of medical journal association (ICJME), reviewers must report their findings according to each of the items listed in this checklist (**Table 1**)⁽¹¹⁾.

Table 1: MOOSE Checklist for Meta-analyses of Observational Studies

| Item No | Recommendation |
|---------|--|
| 1 | Problem definition |
| 2 | Hypothesis statement |
| 3 | Description of study outcome(s) |
| 4 | Type of exposure or intervention used |
| 5 | Type of study designs used |
| 6 | Study population |
| 7 | Qualifications of searchers (eg, librarians and investigators) |
| 8 | Search strategy, including time period included in the synthesis and key words |
| 9 | Effort to include all available studies, including contact with authors |
| 10 | Databases and registries searched |
| 11 | Search software used, name and version, including special features used (eg, explosion) |
| 12 | Use of hand searching (eg, reference lists of obtained articles) |
| 13 | List of citations located and those excluded, including justification |
| 14 | Method of addressing articles published in languages other than English |
| 15 | Method of handling abstracts and unpublished studies |
| 16 | Description of any contact with authors |
| 17 | Description of relevance or appropriateness of studies assembled for assessing the hypothesis to be tested |
| 18 | Rationale for the selection and coding of data (eg, sound clinical principles or convenience) |
| 19 | Documentation of how data were classified and coded (eg, multiple raters, blinding and interrater reliability) |
| 20 | Assessment of confounding (eg, comparability of cases and controls in studies where appropriate) |
| 21 | Assessment of study quality, including blinding of quality assessors, stratification or regression on possible predictors of study results |
| 22 | Assessment of heterogeneity |
| 23 | Description of statistical methods (eg, complete description of fixed or random effects models, justification of whether the chosen models account for predictors of study results, dose-response models, or cumulative meta-analysis) in sufficient detail to be replicated |
| 24 | Provision of appropriate tables and graphics |
| 25 | Graphic summarizing individual study estimates and overall estimate |
| 26 | Table giving descriptive information for each study included |
| 27 | Results of sensitivity testing (eg, subgroup analysis) |
| 28 | Indication of statistical uncertainty of findings |
| 29 | Quantitative assessment of bias (eg, publication bias) |
| 30 | Justification for exclusion (eg, exclusion of non-English language citations) |
| 31 | Assessment of quality of included studies |
| 32 | Consideration of alternative explanations for observed results |
| 33 | Generalization of the conclusions (ie, appropriate for the data presented and within the domain of the literature review) |
| 34 | Guidelines for future research |
| 35 | Disclosure of funding source |

Study Selection and Eligibility Criteria:

The present review included studies that fulfilled the following criteria:

- (1) Studies that included patients with achondroplasia;
- (2) Studies that assessed the efficacy and safety of limb lengthening for limb discrepancy associated with achondroplasia;
- (3) Studies that compared limb lengthening with none or any comparison;
- (4) Studies that reported any of the following outcomes: gained height of femur and tibia, percentage of gained height of femur and tibia, healing index in femur and tibia, satisfaction, complications, and quality of life assessed by SF-36 and Rosenberg self-esteem score;
- (5) Studies that were either prospective or retrospective studies.

We excluded non-English studies, theses, dissertations and conference abstracts.

Search Strategy and Screening

An electronic search was conducted from the inception till September 2018 in Medline via PubMed. We used different combinations of the following queries: achondroplasia, limb lengthening, and gained height.

Screening:

Retrieved citations were imported into EndNote X7 for duplicates removal. Subsequently, unique citations were imported into an Excel sheet and screened by two independent reviewers; the screening was conducted in two steps: title and abstract screening, followed by a full-texts screening of potentially eligible records.

Data Extraction:

Data entry and processing were carried out using a standardized Excel sheet and reviewers extracted the data from the included studies. The extracted data included the following domains: (1) Summary characteristics of the included studies; (2) Baseline characteristics of studied populations; and (3) Study outcomes. All reviewers' independently extracted data from the included articles and any discrepancies were solved by discussion.

Dealing with Missing Data:

Missing standard deviation (SD) of mean change from baseline was calculated from standard error or 95% confidence interval (CI).

Data Synthesis

Continuous outcomes were pooled as mean difference (MD) or standardized mean difference (SMD) using inverse variance method, and dichotomous outcomes will be pooled as relative risk (RR) using Mantel-Haenszel method. The random-effects method was used under the assumption of existing significant clinical and methodological heterogeneity. We performed all statistical analyses using Review Manager (RevMan) 5.3 for windows.

Assessment of Heterogeneity:

We assessed heterogeneity by visual inspection of the forest plots, chi-square, and I-square tests. According to the recommendations of Cochrane Handbook of Systematic Reviews and meta-analysis, chi-square p-value less than 0.1 denote significant heterogeneity while I-square values show no important heterogeneity between 0% and 40%, moderate heterogeneity from 30% to 60%, substantial heterogeneity from 50% to 100%.

RESULTS

Characteristics of the included studies

In the present study, 150 records were retrieved after online PubMed searching. We then retained 32 potentially eligible records for full-texts screening. Finally, 17 studies were included in the present systematic review and meta-analysis (**Figure 1**).

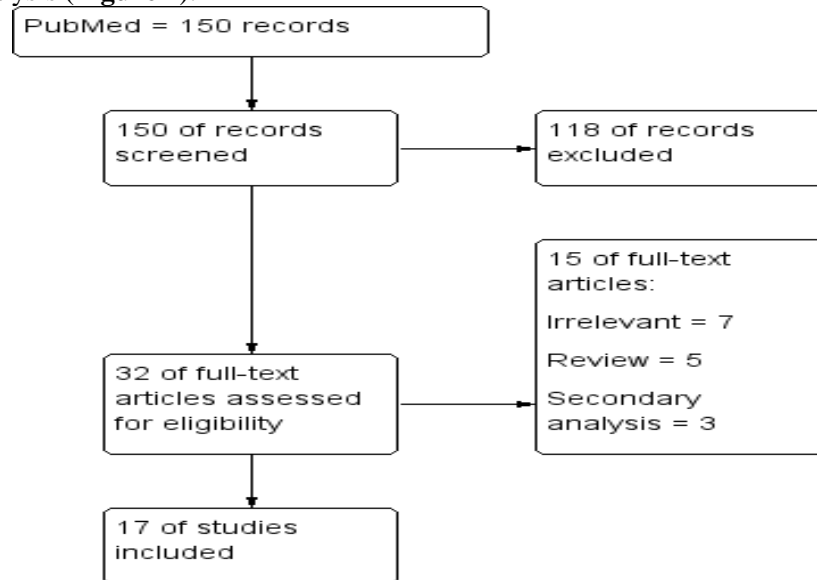

Figure 1: PRISMA flow-chart

Seventeen studies (No. of achondroplasia patients = 466) were included in the present review. Four studies were conducted in Italy, six studies were conducted in Korea, two in Japan, and one study in each of the following countries: US, UK, India, Spain, and France. The majority of the included studies (No. =14) were retrospective studies, one was prospective study, one was case-series study, and one was survey study. While most of included studies recruited heterogeneous group of patients who required lengthening of upper or lower limb, the majority of patients in all included studies were achondroplasia patients. The sample size of the included studies ranged from 8 to 140 patients and the duration of follow up ranged from 6 months to 23 years. Three studies assessed the effects of surgical correction of achondroplasia on psychologic aspects of patients using Rosenberg self-esteem score; the studies concluded that the quality of life increased significantly after limb lengthening. One study assessed the function of lengthened limbs, evaluated by physical strength tests, and reported that it was better at follow-up than before lengthening in the growing children. While the rest of included studies assessed the gained length of surgical correction (**Table 2**).

Table 2: Summary Characteristics of the included studies

| Author | Year | Country | Study Design | Population | Sample Size | Device | Follow-up range | Main Results |
|-------------------------|------|------------------|----------------------|---|-------------|--------------------|--------------------|---|
| <i>Lavinie et al.</i> | 1989 | Rome, Italy | Survey Study | Male and female patients with achondroplasia who underwent limb lengthening procedure | 72 | ilizarov apparatus | NA | Long-term research is required to determine effects of surgical correction of achondroplasia from both psychologic and various physical points of view |
| <i>Aldegheri et al.</i> | 1989 | Rome, Italy | Prospective study | Patients with achondroplasia | 140 | Orthofix fixator | 6 months - 2 years | Callotasis has yielded very favorable results. It is less complex than most lengthening methods and has a lower complication rate. |
| <i>Peretti et al.</i> | 1995 | NY, USA | Case-series | Patients with achondroplasia | 28 | NA | 9 months | In 9 years 28 children have undergone limb lengthening, and six of these patients have now completed the first three stages, obtaining a total increase in length from 18 to 23 cm |
| <i>Yasui et al.</i> | 1997 | Saitama, Japan | Retrospective review | Patients with achondroplasia or hypochondroplasia | 42 | | 15 - 23 years | The function of lengthened limbs, evaluated by physical strength tests, was better at follow-up than before lengthening in the growing children, although the mechanical axes of the lengthened bones were not necessarily in correct alignment. |
| <i>Noonan et al.</i> | 2001 | Pamplona, Spain. | Retrospective review | Patients with achondroplasia or hypochondroplasia | 121 | Orthofix fixator | | The results of the present review suggest that the use of healing indices to gauge the final outcome of distraction osteogenesis is questionable; we were unable to discern significance or clinical importance from appropriately adjusted values. |
| <i>Aldegheri et al.</i> | 2001 | Rome, Italy | Retrospective review | Patients with achondroplasia | 140 | Orthofix fixator | 31 months | The authors' recommendation is to start limb elongation of male patients with achondroplasia at the age of 8 years or older, but to delay limb lengthening in female patients with achondroplasia until approximately 15 years |

Limb Lengthening for Achondroplasia...

Regarding the baseline characteristics of the included studies, the total number of achondroplasia patients was 466 patients. The majority of patients were males and the average age at first operation ranged from 6 to 20 years old. All included studies operated on the femur and tibia except three studies; Kim et al, (2011) and Chilbule et al (2016) that operated on humerus as well, while Cattaneo et al (1990) operated on humerus only. The percentage of increased length of operated limbs ranged from 20.5% to 100.7%; while the healing index ranged from 26 to 48 days/cm (Table 3).

Meta-analysis Results

1. Gain in length in femur

Figure 2: Forest plot of the pooled estimates of the change in gain length of femur

In terms of gained length of femur, eleven studies reported the average increase in femur length after limb lengthening procedure. The overall effect estimate showed that limb lengthening procedure achieved a mean increase in femur length by 11.9 (95% CI 9.39 – 14.43) cm.

Figure 3: Forest plot of the pooled estimates of the change in percentage of gained length of femur

In terms of percentage increase in gained length of femur, seven studies reported the percentage increase in femur length after limb lengthening procedure. The overall effect estimate showed that percentage limb lengthening procedure achieved a mean increase in femur length by 36.25 (95% CI 27.09 – 45.4) %.

2. Healing Index in femur

Figure 4: Forest plot of the pooled estimates of the healing index of femur

In terms of healing index of femur, five studies reported the average increase in healing index of femur after limb lengthening procedure. The overall effect estimate showed that limb lengthening procedure achieved anhealing index of femur 30.46 (95% CI 24.326 – 36.59) days/cm.

3. Gain in length in tibia

Figure 5: Forest plot of the pooled estimates of gained length of tibia

In terms of gained length of tibia, eleven studies reported the average increase in tibia length after limb lengthening procedure. The overall effect estimate showed that limb lengthening procedure achieved a mean increase in tibia length by 9.5 (95% CI 8.169 – 10.927) cm.

Figure 6: Forest plot of the pooled estimates of percentage gained length of tibia

In terms of percentage increase in gained length of tibia, eight studies reported the percentage increase in tibia length after limb lengthening procedure. The overall effect estimate showed that percentage limb lengthening procedure achieved a mean increase in tibia length by 43.49 (95% CI 31.25 – 55.58) %.

4. Healing Index in tibia

Figure 7: Forest plot of the pooled estimates of healing index of tibia

In terms of healing index of tibia, five studies reported the average increase in healing index of tibia after limb lengthening procedure. The overall effect estimate showed that limb lengthening procedure achieved a healing index of tibia of 32.09 (95% CI 18.65 – 25.52) days/cm.

5. Quality of life:

Figure 8: Forest plot of the pooled estimates of Rosenberg self-esteem score

In terms of Rosenberg self-esteem score, two studies compared limb lengthening to no treatment control group. The overall effect estimate showed that limb lengthening significantly improved the quality of life (MD 3.1 95% CI 2.25 – 3.94).

DISCUSSION

Achondroplasia is the most common genetic skeletal dysplasia. It is characterized by a rhizomelic form of dwarfism, exaggerated lumbar lordosis, a prominent forehead and a low nasal bridge. The trunk is generally of near normal length. The incidence of achondroplasia is approximately 1 in 25000 people ⁽¹²⁾.

Limb lengthening remains controversial in patients with achondroplasia. Bilateral lower-limb lengthening has been commonly performed for patients with achondroplasia, as it improves the quality of life (QOL) in selected patients ⁽¹³⁾.

Limb lengthening is associated with a high complication rate, particularly stiffness of adjacent joints and fractures leading to a poor outcome. Many authors suggest a goal of lengthening a bone segment to 20% of its original length ⁽⁵⁾.

The high risk of complications needs to be carefully balanced against any potential cosmetic gains. Improved techniques and understanding of distraction osteogenesis in limb lengthening has led to an increase in the number of limb lengthening procedures and more successful outcomes. In addition the rhizomelic pattern of dwarfism in achondroplasia lends itself favorably to limb lengthening to restore more normal body proportionality ⁽¹²⁾.

In this systematic review and meta-analysis study, we included 17 studies (No. of achondroplasia patients = 466). Four studies were conducted in Italy, six studies were conducted in Korea, two in Japan, and one study in each of the following countries: US, UK, India, Spain, and France. The majority of the included studies (No. =14) were retrospective studies, one was prospective study, one was case-series study, and one was survey study. While most of included studies recruited heterogeneous group of patients who required lengthening of upper or lower limb, the majority of patients in all included studies were achondroplasia patients. The sample size of the included studies ranged from 8 to 140 patients and the duration of follow up ranged from 6 months to 23 years. Three studies assessed the effects of surgical correction of achondroplasia on psychologic aspects of patients using Rosenberg self-esteem score; the studies concluded that the quality of life increased significantly after limb lengthening. One study assessed the function of lengthened limbs, evaluated by physical strength tests, and reported that it was better at follow-up than before lengthening in the growing children. While the rest of included studies assessed the gained length of surgical correction.

This was in concordance with the previous meta-analysis conducted by **Jauregui et al.** ⁽¹⁴⁾, which included seven studies evaluated a total of 192

cases of limb lengthening and averaged 27 limbs lengthened per study. One hundred fifty-three patients comprised of 118 males and 35 females with a mean weighted age of 26 years (range of means 8 to 39 years) underwent limb lengthening procedure. The included studies operated on tibiae 155 cases, femora 25 cases, and humeri 12 cases.

In another systematic review and meta-analysis performed by **Schiedel et al.** ⁽¹⁵⁾, who included 12 studies dating from the last 20 years; three tibial study groups and two groups with only femoral lengthening while the remaining eight studies are reporting about femoral and tibial lengthening procedures. The range of average ages in 12 reports, independently of the absolute numbers of patients, was 8.7–16.7 years. Overall, using the age ranges at the time of the first operation given in 11 of the 12 reports, patients with achondroplasia underwent the first lengthening procedure at ages of between 3 and 35 years. The authors recommend that the operation should be carried out starting at the age of 8 in boys and later in girls, so that at the age of 15 another treatment step for lengthening can take place.

In our study, the percentage of increased length of operated limbs ranged from 20.5% to 100.7%; while the healing index ranged from 26 to 48 days/cm.

Kim et al. ⁽¹²⁾, who performed a retrospective study on 48 segments (24 humeral and 24 femoral) in 12 patients with achondroplasia. All included patients had bilateral lower-limb lengthening two to three years before bilateral humeral lengthening with mean age at the time of the initial surgery was 11.8 years (6.2 to 19.8) to compare the complications of humeral lengthening with those of femoral lengthening. They found that mean gain in length in the femur was 10.2 cm (7.9 to 12.6). The mean lengthening percentage (LP) was 35.2% (29% to 42%) in the femur. The mean healing index (HI) was 34.4 days/cm (17 to 80) in the femur.

In terms of gained length of tibia, eleven studies reported the average increase in tibia length after limb lengthening procedure. The overall effect estimate showed that limb lengthening procedure achieved a mean increase in tibia length by 9.5 (95% CI 8.169 – 10.927) cm and the percentage increase in gained length of tibia, the overall effect estimate showed that percentage limb lengthening procedure achieved a mean increase in tibia length by 43.49 (95% CI 31.25 – 55.58) %. While the healing index of tibia, the overall effect estimate showed that limb lengthening procedure achieved a healing index of tibia of 32.09 (95% CI 18.65 – 25.52) days/cm.

Vaidya et al. ⁽¹⁶⁾, performed a study between 2000 and 2004 on 24 achondroplastic patients with average age at the time of surgery was 12.9 ± 7.48 years (4-35 years), with bifocal tibial osteotomy with gradual deformity correction and lengthening by application of Ilizarov ring fixator in 47 tibiae. They found that the average tibial length at the time of surgery was 16.2 ± 2.3 cm (11.5- 20.8 cm). The total amount of tibial lengthening exceeded 40% and the average tibial healing index was 26.06 ± 3.27 days/cm (range, 21- 35 days/cm).

Regarding complications, they were many complications reported after limb lengthening procedure.

Our study reported some of these complications such as knee contractures, hip flexion contractures, bony complication, pin tract infection, equinus contractures, recurrent deformities, malalignments, fracture, neuropraxia.

In terms of Rosenberg self-esteem score, two studies compared limb lengthening to no treatment control group The overall effect estimate showed that limb lengthening significantly improved the quality of life (MD 3.1 95% CI 2.25 – 3.94).

Similarly, **Kim et al.** ⁽¹²⁾, reported in their retrospective study that the Rosenberg score was higher ($p < 0.001$) for the surgical than for the nonsurgical group: 22.1 ± 2.5 versus 19 ± 1.6 , respectively which means there was a significant improvement in the quality of life between the surgical and nonsurgical groups.

CONCLUSION

In conclusion, limb lengthening is a reliable procedure with a relatively low complication rate in increasing the length of femur and tibia in patients with achondroplasia. The limb lengthening significantly increase the length of both femur and tibia. Moreover, the procedure significantly improve the quality of life of the patients. Nevertheless, the quality of included studies were low and further high quality studies are still needed.

RECOMMENDATIONS

- Limb lengthening is a reliable procedure with a relatively low complication rate
- Therefore. The procedure can be used to increase the length of femur and tibia in patients with achondroplasia. and improve their quality of life.
