Abstract

Through heating processes, electrical conductivity plays a crucial role in the food industry. The effects of Joule heating and temperature-dependent electrical conductivity on the boundary layer flow of micropolar fluid were the main topics of this paper. Considerations include thermal radiation, activation energy, and microstructural/multiple slips effects. The resulting partial differential equations system (PDEs) is transformed into a nonlinear ordinary differential equations model using the proper similarity variables (ODEs). The shooting technique, a highly reliable/accurate technique, is used to obtain semi-analytical results. In Mathematica 13.1.1, apply the generalised differential transform method (GDTM), Dawar 2021 newly published results are used to approve/confirm the accuracy of the acquired results. Findings demonstrate that the parameter of temperature-dependent electrical conductivity enhances fluid temperature and increases energy gain in the heating operation system, which is important for the design of Ohmic heaters (food industry processes).

Keywords: Non-constant electrical conductivity; Microstructure/multiple slip; Activation energy; Micropolar fluid; Mathematica 13.1.1.

Introduction

When materials are cooled to extremely low temperatures, a phenomenon known as electrical conductivity/specific conductance takes place, where superconductors allow electricity to travel through without experiencing any electrical resistance. For the initial definition of electrical conductivity [1]. Kamerlingh Onnes conducted tests in 1911 to determine whether the Metal resistance at low temperatures would continue to drop linearly with the reduction in temperature or would be fixed at a particular value. The causes of electrical conductivity and its many applications, such as in electrical operations like particle accelerators, digital electrical circuits, and magnetic resonance imaging devices, as well as in medical processes like magnetic resonance, cables superconductivity, were first studied by researchers, investigators, and modelers [2–6]. Obalalu et al. [7] modification of the conductivity of electricity influence on the flow of Casson nanofluid was introduced in the context of fluids. They proposed that the link between fluid temperature and electrical conductivity is inverse. The impact of Joule dissipation in peristaltic nanofluid flow was instead

researched by Qasim et al. [8]. They suggested that there is a direct correlation between electrical conductivity and fluid temperature. This work introduces a novel theoretical perspective on the relationship between fluid temperature and electrical conductivity. We should investigate the experimental relationship between electrical conductivity and fluid temperature before making a judgement regarding this relationship. As a result, every experiment that has been done has demonstrated a connection between electrical conductivity and fluid temperature.

In applications like micro-pumps, hard disc drives, micro-valves, and nozzles, slip flows are regarded as the most important problem of microsystems. Dawar et al. [9] investigate the impact of first and second-order slip flow on the MHD micropolar boundary layer flow. They claimed that compared to a non-microstructural slip, a microstructural slip has a greater visible effect on the distribution of velocity due to high magnetic parameter values. Mabood and Shateyi [10] thought carefully about the effects of heat radiation and numerous slips on an unstable flow with sheets that are stretched. They discovered that the slip parameter's values result in a drop in fluid velocity close to the

boundary layer. Mahmoud and Waheed [11] discussed how magnetic fields affect micropolar fluid flow. Afzal and Aziz [12] investigated the impact of MHD slip and changing thermal conductivity on nanofluid flow with heat and mass transfer. Numerous researchers and modelers have explored the effects of slip on flow and its applications in this direction [13-20].

We selected a highly numerical methodology termed by shooting method combination with Runge-Kutta method to produce the results/solutions of the MHD boundary layer flow of micropolar fluid that are provided in the current work (ODE45). The shooting method is typically thought of as a highly constructive method in numerical analysis that uses dropping the boundary value problem to an initial value problem to solve it. Up until a solution is found that also fulfils the boundary value problem's boundary conditions, it entails finding initial value problem solutions for a variety of initial conditions. Merle proposed the shooting method in 1988 [21], and it was he who found the solution to the nonlinear Dirac equations. The shooting technique was first used by Hasanuzzaman et al. [22] to solve the Problem with MHD boundary layer flow involving the influence of transpiration. MHD Casson Nanofluid Laminar Boundary Layer Flow was investigated by Lanjwani et al [23] using the shot method. The shooting approach is frequently used by authors and researchers to find answers to numerous boundary value problems [24–28].

The primary goal of this investigation is to provide a novel theoretical framework for the impacts of temperature-dependent electrical conductivity, microstructure, and multiple slips on the MHD boundary layer flow of micropolar fluid by employing a very precise method known as the shot method. The proposed model's solution is presented in two separate scenarios, the first involving a viscous fluid ($\alpha=0$), and the second using a micropolar fluid ($\alpha=1$). Results for temperature gradients, velocity gradients, and distributions of the concentration of nanoparticles are provided in various mentioned instances. With the help of Mathematica 13.1.1 and advanced shooting method algorithms, the findings given were obtained.

Experimental

Consideration is given to the flow of micropolar fluid within a stretching sheet. Conditions for a microstructure slide are taken into account. The velocity of the stretching sheet is supposed to $u_s = ax$ where (a) the stretching rate. Applied magnetic field B_0 strength in the y-axis of constant value. In view of the formulated problem, the governing equations can take the form [20]:

$$\frac{\partial u'}{\partial x'} + \frac{\partial v'}{\partial y'} = 0, \quad (1)$$

$$u' \frac{\partial u'}{\partial x'} + v' \frac{\partial u'}{\partial y'} = \frac{\kappa}{\rho} \frac{\partial N'}{\partial y'} + \frac{\partial^2 u'}{\partial y'^2} - \frac{\sigma(T', C') B_0^2}{\rho} u' + g\{\beta_C(C' - C'_\infty) + \beta_T(T' - T'_\infty)\}, \quad (2)$$

$$u' \frac{\partial N'}{\partial x'} + v' \frac{\partial N'}{\partial y'} = \frac{\Omega}{\rho_j} \frac{\partial^2 N'}{\partial y'^2} - \frac{\kappa}{\rho_j} \left(2N' + \frac{\partial N'}{\partial y'} \right), \quad (3)$$

$$u' \frac{\partial T'}{\partial x'} + v' \frac{\partial T'}{\partial y'} = \frac{k}{\rho c_p} \left(1 + \frac{16}{3} \frac{\sigma^* T_0^3}{\kappa k^*} \right) \frac{\partial^2 T'}{\partial y'^2} + \frac{\sigma(T', C') B_0^2}{\rho c_p} u'^2 + \tau \left[D_B \frac{\partial T'}{\partial y'} \frac{\partial C'}{\partial y'} + \frac{D_B}{D_T} \left(\frac{\partial T'}{\partial y'} \right)^2 \right], \quad (4)$$

$$u' \frac{\partial C'}{\partial x'} + v' \frac{\partial C'}{\partial y'} = D_B \frac{\partial^2 C'}{\partial y'^2} + K_r^2 (C' - C'_\infty) \left(\frac{T'}{T'_\infty} \right)^n e^{\left(\frac{-E_a}{\kappa_B T'} \right)}. \quad (5)$$

Where, the spin (Ω) gradient velocity which defined as the follows:

$$\Omega = \mu \left(1 + \frac{\alpha}{2} \right) j, \quad (6)$$

Here, the micropolar ($\alpha = \frac{\kappa}{\mu}$) parameter.

The chosen/appropriate boundary conditions are described as follows [9]:

$$u' = u_s + u_{slip}, v' = 0, N' - n \frac{\partial u'}{\partial y'}, T' = T'_s, C' = C'_s \text{ at } y = 0, \quad (7)$$

$$u' \rightarrow 0, N' \rightarrow 0, T' \rightarrow T'_\infty, \text{ and } C' \rightarrow C'_\infty \text{ as } y \rightarrow \infty \quad (8)$$

Here, the micro-rotation (n) parameter, the fluid (C, C_s) nanoparticles concentration and nanoparticles concentration near the surface, the ambient fluid (C_∞) nanoparticles concentration, the coefficient of (D_B) Brownian diffusion, the coefficient of thermophoretic (D_T) diffusion, the gravitational (g) acceleration, the thermal (k) conductivity, the coefficient of mean (k^*) absorption, the Stefan-Boltzmann (σ^*) constant, the fluid (T, T_s) temperature and temperature near to the surface, the nanoparticles concentration (β_C) expansion, the thermal (β_T) expansion, the vortex (κ) viscosity, the dynamic (μ) viscosity. $\sigma(T', C')$ is the variable electrical conductivity, which defined as:

$$\sigma = \sigma_0 \left[1 + \epsilon \left(\frac{T' - T'_\infty}{T'_s - T'_\infty} \right) + \beta \left(\frac{C' - C'_\infty}{C'_s - C'_\infty} \right) \right], \quad (9)$$

Here, σ_0 is the constant electrical conductivity case, ϵ is the temperature-dependent electrical conductivity parameter and β is the nanoparticles concentration-dependent electrical conductivity parameter.

The appropriate transformations are proposed:

$$\psi = \sqrt{avx} f'(\eta), u = \frac{\partial \psi}{\partial y}, v = \frac{\partial \psi}{\partial x}, N = ax \sqrt{\frac{a}{2v}} g(\eta), \quad \eta = y \sqrt{\frac{a}{v}}, \theta(\eta) = \frac{T' - T'_\infty}{T'_s - T'_\infty} \text{ and } \phi(\eta) = \frac{C' - C'_\infty}{C'_s - C'_\infty}. \quad (10)$$

Here η is the similarity variable, $f(\eta)$ is the non-dimensional stream function, $f'(\eta)$ axial velocity, $\theta(\eta)$ is the temperature, $g(\eta)$ is the micropolar particles rotation, and $\phi(\eta)$ nanoparticles volume fraction, correspondingly. The governing system of differential equations are transformed/ non-dimensional as follows.

$$(1 + \alpha) f'''' + f f'' - f'^2 - \alpha g' + \gamma_1 \theta + \gamma_2 \phi - M(1 + \epsilon \theta + \beta \phi) f' = 0, \quad (11)$$

$$\left(1 + \frac{\alpha}{2} \right) g'' + f g' - g f' - \alpha (f'' + 2g) = 0, \quad (12)$$

$$\frac{(1+R_d)\theta''}{Pr} + Nb \theta' \phi' + Nt \theta'^2 + S \theta + E_c (1 + \alpha) f''^2 + f \theta' + M (1 + \epsilon \theta + \beta \phi) E_c f'^2 = 0, \quad (13)$$

$$\phi'' + f \phi'(\eta) + \frac{Nt}{Nb} \theta''(\eta) - Pr L_e (1 +$$

$$\delta \theta(\eta))^n e^{\left(\frac{-E}{1+\delta\theta(\eta)}\right)} \phi(\eta) = 0. \quad (14)$$

With boundary conditions:

$$f(0) = 0, f'(0) = 1 + \gamma f''(0) + \delta_1 f'''(0) + R_0 g'(0), g(0) = -m f'', \theta(0) = 1, \phi(0) = 1, \quad (15)$$

$$f'(\infty) = 0, g(\infty) = 0, \theta(\infty) = 0, \phi(\infty) = 0. \quad (16)$$

Where, $M = \frac{2\sigma_0 B_0^2}{\rho a}$ is the Hartmann number, $K_p = \frac{2v}{a K p_0}$ is the porous parameter $Pr = \frac{\nu}{\alpha}$ is the Prandtl number, $R_d = \frac{16 \sigma^* T_\infty^3}{3 k k^*}$ is the radiation parameter

$E_c = \frac{u_s^2}{c_p (T_s - T_\infty)}$ is the Eckert number, $S = \frac{2tQ_0}{a \rho c_p}$ is the heat source factor

$Nb = \frac{\tau D_B (C_w - C_\infty)}{\nu}$ is the Brownian motion parameter, $Nt = \frac{\tau D_T (T_s - T_\infty)}{\nu T_\infty}$ is the thermophoresis parameter,

$\lambda = \frac{v_0}{\sqrt{a\nu}}$ is the transpiration parameter, species, $L_e = \frac{\nu}{D_B}$ is the Lewis number, $\delta = \frac{T_s' - T_\infty'}{T_\infty'}$ is the temperature difference parameter and $E = \frac{E_a}{K_B T'}$ is the Activation energy.

By using the proper similarity variables and boundary conditions, the ordinary differential equations system (11–14) is transformed into a nondimensional system (15–16). Utilizing the superposition technique, the Higher-order values are extracted using the GDTM technique after obtaining the initial conditions and first order of the differential equation. The answers of differential equations system can be obtained accurately and efficiently using this method [29–31].

The general n^{th} order ordinary differential equation can be written as:

$$y(t, f, f', \dots, f^{(n)}) = 0. \quad (17)$$

This equation is subjected to the initial guess.

$$f^{(k)}(0) = d_k, \quad k = 0, \dots, n-1. \quad (18)$$

Let $f(t)$ be analytic in a domain D and let $t = t_0$ represent any point in D . The k^{th} derivative transformation of a function $f(t)$ can be defined as follows:

$$F(k) = \left(\frac{1}{k!}\right) \left[\left(\frac{d^{(k)}f(t)}{dt^{(k)}}\right)\right]_{(t=t_0)}, \quad \forall t \in D. \quad (19)$$

Results and discussion

Here, the velocity, micro-rotation velocity, temperature, and nanoparticle concentration are numerically analysed for different values of the physical components involved in the problem to emphasise the implications of these parameters in more detail. The values listed below are also used as the benchmark for these parameters:

$$\alpha = 0.1, Nb = 0.2, Nt = 0.3, S = 0.2, \gamma_1 = 1, \gamma_2 = 0.8, E_c = 0.2, \epsilon = 0.2, \beta = 0.2, E = 2, \delta = 0.1, R_d = 1, \gamma = 0.7, m = 0.4, \delta_1 = -1, R_0 = 0.1, Pr = 1, L_e = 0.2$$

The dimensionless viscosity ratio α measures the relative strengths of the vortex viscosity coefficient to the viscosity coefficient. The coefficients listed here are higher than or equal to 0. For example, the blood, $\alpha = 0.08$. Figs. (1) and (2) show the change of the velocity f' versus the dimensionless coordinate η for different values of thermal Grashof number γ_1 and the dimensionless viscosity ratio α in case of temperature and nanoparticles concentration depend on electrical conductivity, respectively. It is seen, from these figures that the velocity increases with the increase of γ_1 , whereas it decreases as α increases, this is due to the fact that the effect of the viscosity coefficient on fluid flow creates a resistance force which may decrease the fluid motion. For large values of α , the velocity decreases with η till a definite value $\eta = \eta_0$ (represents the minimum value of f') and it increases afterwards. The effects of the slip velocity parameter γ on the velocity which is a function of η are shown in Fig. (3). It is found that the velocity f' distribution decreases by increasing γ in the interval $\eta \in [0, 2.4]$; otherwise, it increases by increasing η . So, the behavior of g in the interval $\eta \in [0, 2.4]$, is an inversed manner of its behavior in the interval $\eta \in [2.4, 5]$ except that the curves are very close to each other than those obtained in the first interval.

Fig. 1 The velocity component is plotted against η for the variation value of γ_1 .

Fig. 2 The velocity component is plotted against η for the variation value of α .

Fig.3. the velocity component is plotted against η for the variation value of γ .

The effects of the dimensionless viscosity ratio α in case of temperature and nanoparticles concentration don't depend on electrical conductivity on the microrotation g which is a function of η are shown in Fig. (4). It is found that the microrotation distribution increases by increasing α . Moreover, for large values of α , the microrotation increases with η till a definite value $\eta = \eta_0$ (represents the maximum value of g) and it decreases afterwards. Figs. (5) and (6) show the behavior of the microrotation g with the dimensionless coordinate η for various values of the magnetic field parameter M and the thermophoresis parameter Nt , respectively. It has been noticed that the microrotation distribution increases by increasing M in the interval $\eta \in [0, 1.3]$; otherwise, it decreases by increasing η . While the effect of Nt is to decrease g in the interval $\eta \in [0, 2.1]$, and it has an inversed manner in the interval $\eta \in [2.1, 5]$ except that the curves are very close to each other than those obtained in the first interval. In this case, for large values of M , and small values of Nt there is a maximum value of g holds at $\eta \cong 0.4$. The effects of the other parameters are recorded to be similar to them; these figures are left out here to avoid repetition.

Figs. (7) and (8) show the behavior of the temperature θ with the dimensionless coordinate η for various values of the thermophoresis parameter Nt and thermal Grashof number γ_1 , respectively. It has been noticed that the temperature increases with the increases of Nt , while it decreases as γ_1 increases. It is also noted that for each value of both Nt and γ_1 , θ decrease as η increases and the relation between θ and η seems as a hyperbolic.

The result in Fig. (7) is caused by the thermophoresis effect, which is a force caused by the temperature difference between the hot liquid and the cold wall that moves the particles towards the cold wall.

Fig. 4 The microrotation velocity is plotted against η for the variation value of α .

Fig. 5 The microrotation velocity is plotted against η for the variation value of M .

Fig. 6 The microrotation velocity is plotted against η for the variation value of Nt .

Fig. 7 The temperature is plotted against η for the variation value of Nt .

Fig. 8 The temperature is plotted against η for the variation value of γ_1 .

Fig. 10 The nanoparticles concentration is plotted against η for the variation value of σ .

The variations of the nanoparticle's concentration distribution φ with the dimensionless coordinate η for various values of activation energy parameter E_a and the reaction parameter σ are displayed in Figs. (9) and (10), respectively. The graphs in Figs. (9) and (10) show that as the parameter E_a is increased, the nanoparticle concentration distribution also increases, while it decreases by increasing the parameter α , respectively. It is also noted that for small values of E_c and large values of σ , the relation between φ and η is a parabola, i.e. φ increases with η till a definite value $\eta = \eta_0$ (represents the maximum value of φ) and it decreases afterwards. This maximum value of φ increases by increasing E_a , while it decreases by increasing σ . The results which are obtained in Fig. (10), are consistent with the findings of Eldabe et al. [32]. Other parameters have an effect on the temperature, but they are recorded to be similar to those obtained in Fig. (9) and (10). In order to preserve space, figures are not included here. Figure (11) displays the effect of magnetic field parameter M on the nanoparticle's concentration distribution φ which is a function of η . It is found that the nanoparticles concentration decreases by increasing M in the interval $\eta \in [0, 1.43]$; otherwise, it increases by increasing η . So, the behavior of φ in the interval $\eta \in [0, 1.43]$, is an inversed manner of its behavior in the interval $\eta \in [1.43, 5]$, and in the first interval, there is a maximum value of φ holds at $\eta = 0.44$.

Fig. 9 The nanoparticles concentration is plotted against η for the variation value of E_a .

Fig. 11 The nanoparticles concentration is plotted against η for the variation value of M .

Conclusion

The activation energy effect as well as temperature and nanoparticle concentration-dependent conductivity are both included in this problem, expanding upon the work of [20]. The velocity, temperature, and concentration extremely nonlinear partial differential equations are transformed into nonlinear ordinary differential equations using the appropriate transforms. By using DTM and a program from the MATHEMATICA package, we were able to numerically solve this set of equations. The current analysis can act as a model that could aid in understanding physiological flux mechanics [33–53]. Following is a summary of the results that were attained.

1. By increasing both Nt and γ_1 , the velocity increases while it decreases as α , M and β increase. Moreover, it increases or decreases as γ increases.
2. The microrotation velocity distribution increases or decreases as Nt , γ_1 , α , M , γ and β increase.
3. The microrotation velocity becomes greater with increasing the dimensionless coordinate η and reaches maximum value, after which, it decreases.
4. The temperature distribution increases as Nt , α , M , γ and β increase, while it decreases when γ_1 increases. Furthermore, it increases or decreases as the problem's other physical parameters increase.
5. The nanoparticles concentration behavior is contrary with respect to the temperature behavior except that it decreases as α and σ increase.
