# HYDROMAGNETIC STABILITY OF A STREAMING COMPRESSIBLE GAS CYLINDER IN A LIQUID FOR( m=0)MODE 

Ahmed E. Radwan*, and Hussain E. Hussain**

#### Abstract

The hydromagnetic instability of compressible hollow jet involved with surface tension is discussed in the axisymmetric mode for all short and long wavelengths. The dispersion relation is derived and discussed analytically and numerically. The axial magnetic fields inside the gas and liquid regions have stabilizing effects for all short and long wavelengths. This is physically interpreted that the axial field exerts a strong effect which causes the bending and twisting of the magnetic lines of force. The compressibility effects need careful treating. Here the incompressible fluid result is obtained as $a$ tends to $\infty$ ( $a$ is the sound speed in the fluid). For finite value of $a$ (i.e. compressible fluid), the temporal amplification is larger than that in the incompressible case. So the compressibility has a strong destabilizing tendency and increase the unstable domains. The streaming is destabilizing for all short and long wavelengths. The capillary force is destabilizing for small wave numbers while it is stabilizing for all the rest wavelengths. Whatever the stabilizing effect of the electromagnetic force is strong enough, the capillary, streaming and compressible instability could not be suppressed and the model will be always unstabl

## KEY WORDS:

Compressible, Gas Cylinder, Hydromagnetic and Streaming

[^0]
## INTODUCTION

The stability and oscillation of full liquid jet endowed with surface tension or/and acted by electromagnetic force have been documented in several reported works based on the linear perturbation technique of small disturbance. See Rayligh (1945), Lin (1976), Drazin and Reid (1980), Chandrasekhar (1981), Avital (1995) and Radwan (2004). The instability of hollow jet ( gas cylinder penetrated in a liquid) acted by surface tension only is envised and studied for first time in the scientific province by Chandrasekhar ( for axisymmetric mode ( $\mathrm{m}=0$ ) , m is the azimuthally wave number)only . Also Drazin and Reid (1980) and Kendall (1986) gave an idea about such problem to be done mathematically for axisymmetric and nonaxisymmetric . In such work Channdrasekhar (1981), the inertia of the liquid is considered to be predominate over that of the gas and consequently the gas inertia force is neglected. Cheng (1985) elaborated the capillary stability of a streaming gas jet in a liquid, taking into account the inertia of both incompressible gas and liquid. However one has to infer here that the result given by Cheng (1985), in Eqs. (4) and (5), are incorrect in the third term. In fact the term $\left(1-s^{2}-k^{2} R_{o}^{2}\right)$ must be in the numerator as it is clear from Eq.(3) in(1985). See also equations (45),(46) and (48) in the present work and Drazin \& Reids result (1980) p. 16 and also Chandrasekhar's dispersion relation (1981) p. 538 and p. 540 (Eqs. (147) and (155) there). Radwan(1991) has examined the effect of a magnetic field on the capillary instability of an incompressible inviscid hollow jet.

Here we extend the latter works by considering the liquid is compressible, which means that the velocity is not solinoidal and that the density is not constant.

## BASIC STATE

We consider a hollow jet which is a gas cylinder pervaded into a liquid. In the initial state the gas cylinder is of radius Ro. The liquid is assumed to be non-viscous, perfectly conducting and compressible (i.e. its density $\rho$ will not be constant) and pervaded by the uniform magnetic field $\underline{H}_{o}=\left(0,0, H_{o}\right)$. The gas is pervaded by the uniform magnetic field $\underline{H}_{o}^{g}=\left(0,0, \alpha H_{o}\right)$ where $H_{0}$ is the intensity of the magnetic field in the unperturbed state, while $\alpha$ is parameter satisfying certain restriction. The components of the vector fields $\underline{H}_{o}$ and $\underline{H}_{0}{ }^{\mathrm{g}}$ are considered along the cylindrical coordinates $(r, \varphi, z)$ system with the z -axis coinciding with the axis of the hollow model jet. Each of the gas and liquid is considered with constant magnetic permeability.

The acting forces on the present model of a compressible hollow jet are the electromagnetic, pressure gradient and capillary forces. Under the present circumstances, the MHD basic equations for describing the motion of a compressible fluid model are given as follows. See Lamb (1959), Roberts (1967), Bernstein (1983), Mayer (1987) and Radwan (2005).

In the liquid
The equation of motion

$$
\begin{equation*}
\rho\left(\frac{\partial \underline{u}}{\partial t}+(\underline{u} \cdot \nabla) \underline{u}\right)=-\nabla P+\mu(\nabla \wedge \underline{H}) \wedge \underline{H} \tag{1}
\end{equation*}
$$

Equation of continuity

$$
\begin{equation*}
\frac{\partial \rho}{\partial t}+\nabla \cdot(\rho \underline{u})=0 \tag{2}
\end{equation*}
$$

Equation of conservation of energy

$$
\begin{equation*}
\rho C_{v}\left(\frac{\partial T}{\partial t}+(\underline{u} \cdot \nabla) T\right)=-P(\nabla \cdot \underline{u}) \tag{3}
\end{equation*}
$$

Equation of state

$$
\begin{equation*}
P=K \rho^{\gamma} \tag{4}
\end{equation*}
$$

Gauss' law

$$
\begin{equation*}
\nabla \cdot \underline{H}=0 \tag{5}
\end{equation*}
$$

Evaluation equation of magnetic field in perfectly conducting fluid

$$
\begin{equation*}
\frac{\partial \underline{H}}{\partial t}=\nabla \wedge(\underline{u} \wedge \underline{H})=(\underline{H} \cdot \nabla) \underline{u}-\underline{H}(\nabla \cdot \underline{u})-(\underline{u} \cdot \nabla) \underline{H} \tag{6}
\end{equation*}
$$

In the gas region

$$
\begin{align*}
& \nabla \cdot \underline{H}^{\text {gas }}=0  \tag{7}\\
& \nabla \wedge \underline{H}^{\text {gas }}=0 \tag{8}
\end{align*}
$$

Along the gas-liquid interface, the surface pressure due to the capillary force is given by

$$
\begin{equation*}
P_{s}=S(\nabla \cdot \underline{N}) \tag{9}
\end{equation*}
$$

with

$$
\begin{equation*}
\nabla \cdot \underline{N}=r_{1}^{-1}+r_{2}^{-1} \tag{10}
\end{equation*}
$$

Here $\underline{u}$ and $P$ are the liquid velocity and kinetic pressure, $\underline{H}$ is the magnetic field intensity, $T$ is the temperature of the liquid, $\mathrm{C}_{\mathrm{v}}$ is the specific heat of constant volume, $\gamma\left(=\left(\mathrm{C}_{\mathrm{p}} / \mathrm{C}_{\mathrm{v}}\right)\right)$ is the ratio of specific heats of the liquid, $S$ is the surface tension coefficient, while $r_{1}$ and $r_{2}$ are the principle radii of curvature. $\underline{\mathrm{N}}$ is, a unit vector outward normal to the performed interface $f(r, z, t)=0$, given by

$$
\begin{equation*}
\underline{N}=\nabla f(r, z, t) /|\nabla f(r, z, t)| \tag{11}
\end{equation*}
$$

In the unperturbed state, we consider the liquid streams with the velocity $\underline{u}_{o}=(0,0, U)$. The unperturbed state is studied and consequently the kinetic pressure of the liquid is given by

$$
\begin{equation*}
P_{o}=-\frac{S}{R_{o}^{2}}+\frac{\mu H_{o}^{2}}{2}\left(\alpha^{2}-1\right)+P_{o}^{\text {gas }} \tag{12}
\end{equation*}
$$

In the absence of the capillary force effect $(S=0)$, the pressure $\mathrm{P}_{\mathrm{o}}$ is positive as long as $(\alpha>1)$. However the model will collapse as $(\alpha=1)$. Also if we neglect the surface tension effect, so $P_{o}^{g}$ must be greater than $\left(S / R_{o}^{2}\right)$ to avoid the collapsing of the model.

## LINEARIZATION

We assume a small axisymmetric disturbance along the gas-liquid interface, then for small departure from the unperturbed state, every physical quantity $\chi(\mathrm{r}, \mathrm{z}, \mathrm{t})$ may be expressed, see Radwan (2004) and (1996) as
$\chi(r, z, t)=\chi_{o}(r)+\varepsilon(t) \chi(r, z)$
where the subscript zero characterizes quantities in the initial state while those with the index unity are their increments. Here $\chi$ stands for $\rho, \mathrm{P}, \underline{\mathrm{u}}, \underline{\mathrm{H}}, \underline{\mathrm{H}}^{\text {gas }}, \underline{\mathrm{N}}$ and the radical distance of the gas cylinder. The amplitude of the perturbation $\varepsilon(\mathrm{t})$ is given by

$$
\begin{equation*}
\varepsilon(t)=\varepsilon_{o} \exp (\sigma t) \tag{14}
\end{equation*}
$$

where $\sigma$ is the growth rate of instability or rather the oscillation frequency if $\sigma(=\mathrm{i} \omega$ with $\mathrm{i}=$ $(-1)^{1 / 2}$ the imaginary factor) is imaginary. Consider an axisymmetric sinusoidal propagating wave along the gas-liquid interface. For a single Fourier term and based on the linearized perturbation technique, the perturbed radial distance of the gas cylinder is being

$$
\begin{equation*}
r=R_{o}+\varepsilon_{o} R_{1} \tag{15}
\end{equation*}
$$

with
$R_{1}=\exp (i k z+\sigma t)$
The second term in the right side of (15) represents the elevation of the surface wave measured from the unperturbed position with k is the longitudinal wave number.

Based on the foregoing expansions, the relevant perturbation equations are given by:

$$
\begin{align*}
& \frac{\partial \underline{u}_{1}}{\partial t}+\left(\underline{u}_{o} \cdot \nabla\right) \underline{u}_{1}-\frac{\mu}{\rho_{o}}\left(\underline{H}_{o} \cdot \nabla\right) \underline{H}_{1}=-\nabla \prod_{1}  \tag{17}\\
& \sigma \underline{H}_{1}=\left(\underline{H}_{o} \cdot \nabla\right) \underline{u}_{1}-\left(\underline{u}_{1} \cdot \nabla\right) \underline{H}_{o}-\left(\underline{u}_{o} \cdot \nabla\right) \underline{H}_{1}-\underline{H}_{o}\left(\nabla \cdot \underline{u}_{1}\right)+\underline{u}_{1}\left(\nabla \cdot \underline{H}_{o}\right)  \tag{18}\\
& \nabla \cdot \underline{H}_{1}=0  \tag{19}\\
& P_{1}=a^{2} \rho_{1}  \tag{20}\\
& \frac{\partial \rho_{1}}{\partial t}+\nabla \cdot\left(\rho_{o} \underline{u}_{1}+\rho_{1} \underline{u}_{o}\right)=0  \tag{21}\\
& \nabla \cdot \underline{H}_{1}^{\text {gas }}=0 \quad, \nabla^{\wedge} \underline{H}_{1}^{\text {gas }}=0 \tag{22}
\end{align*}
$$

and

$$
\begin{equation*}
P_{1 s}=\frac{S}{R_{o}^{2}}\left(R_{1}+R_{o}^{2} \frac{\partial^{2} R_{1}}{\partial z^{2}}\right) \tag{24}
\end{equation*}
$$

Where
$\rho_{o} \Pi_{1}=P_{1}+\frac{\mu}{2}(\underline{H} \cdot \underline{H})_{1}$
is the total magnetohydrodynamic pressure which is the sum of the perturbed kinetic pressure $P_{1}$ of the liquid and the magnetodynamic pressure $(\mu / 2)(\underline{H} \cdot \underline{H})_{1}$, due to electromagnetic acting force. While $a$ is the speed of sound in the compressible liquid defined by:

$$
\begin{equation*}
a=\left(\gamma P_{o} / \rho_{o}\right)^{\frac{1}{2}} \tag{26}
\end{equation*}
$$

By combining equations (20) and (21), we get
$(\sigma+i k U) P_{1}=-\rho_{o} a^{2}\left(\nabla \cdot \underline{u}_{1}\right)$
In view of the time-space dependence and according to the linear perturbation technique used for solving the stability problems of cylindrical models (cf. Chandrasekhar (1981)and Radwan (2005), every fluctuating quantity $\chi_{1}(r, z, t)$ could be expressed as
$\chi_{1}(r, z, t)=\varepsilon_{o} \chi_{1}^{*}(r) \exp (\sigma t+i k z)$
By the use of the expansion (27), the perturbed equations (17)-(24) are solved and the perturbed quantities $\underline{\underline{u}}_{1}, \mathrm{P}_{1}, \rho_{1}, \underline{\mathrm{H}}_{1}, \underline{\mathrm{H}}_{1}{ }^{\mathrm{g}}, \mathrm{T}$ are identified. These variables contain constants due to integration. Such constants may be determined upon applying the following boundary conditions.
(i) The normal component $\mathrm{u}_{\mathrm{r}}$ of the velocity vector $\underline{\mathrm{u}}$ must be compatible with the velocity of the perturbed gas-liquid boundary across the interface (15) at $\mathrm{r}=\mathrm{R}_{\mathrm{o}}$.
This condition yields

$$
\begin{equation*}
u_{1 r}=\frac{\partial R_{1}}{\partial t}+\left(\underline{u}_{o} \cdot \nabla\right) R_{1} \tag{28}
\end{equation*}
$$

(ii) The jump of the normal component of the magnetic field vanishes across the liquid-gas interface at $r=R_{0}$. This condition reads

$$
\begin{equation*}
\underline{\mathrm{N}} .<\underline{\mathrm{H}}>=0 \tag{29}
\end{equation*}
$$

Up to first order, the condition (29) gives

$$
\begin{equation*}
\underline{\mathrm{N}}_{0} \cdot<\underline{\mathrm{H}}_{1}>+\underline{\mathrm{N}}_{1} .<\underline{\mathrm{H}}_{0}>=0 \tag{30}
\end{equation*}
$$

with

$$
\begin{equation*}
\langle\underline{H}\rangle=\underline{H}^{\text {gas }}-\underline{H}^{\text {liquid }} \tag{31}
\end{equation*}
$$

$$
\begin{align*}
& \underline{N}_{o}=(1,0,0)  \tag{32}\\
& \underline{N}_{1}=(0,0,-i k) \exp (\sigma t+i k z) \tag{33}
\end{align*}
$$

(iii) The balance of the normal component of the total stress tensor across the gas-liquid interface at $\left(r=R_{0}\right)$ is being

$$
\begin{equation*}
\rho_{o} \Pi_{1}+R_{1} \frac{\partial P_{o}}{\partial r}+\frac{\mu}{2} R_{1} \frac{\partial\left(\underline{H}_{o} \cdot \underline{H}_{o}\right)}{\partial r}=P_{1 s}+\frac{\mu}{2}\left[\left(\underline{H}^{\text {gas }} \cdot \underline{H}^{\text {gas }}\right)_{1}+R_{1} \frac{\partial\left(\underline{H}_{o}^{\text {gas }} \cdot \underline{H}_{o}^{\text {gas }}\right)}{\partial r}\right] \tag{34}
\end{equation*}
$$

Consequently the authors finally, after calculations, obtained the following.
The total MHD pressure
$\Pi_{1}=-\frac{1}{\eta K_{o}^{l}(y)}\left((\sigma+i k U)^{2}+\Omega_{A}^{2}\right) K_{o}(\eta r) R_{1}$
The magnetic field in the liquid region
$\underline{H}_{1}=\frac{i k H_{o}}{(\sigma+i k U)} \underline{u}_{1}+\frac{H_{o}}{\rho_{o} a^{2}} P_{1} \underline{e}_{2}$
The velocity components of the liquid
$u_{1 r}=-\frac{(\sigma+i k U)}{\left((\sigma+i k U)^{2}+\Omega_{A}^{2}\right)} \frac{\partial \prod_{1}}{\partial r}$
$u_{1 \phi}=0$
$u_{1 z}=i k(\sigma+i k U)\left[-1+\frac{\mu H_{o}^{2}}{\xi a^{2}}\right]\left[(\sigma+i k U)^{2}+\mu k^{2} H_{o}^{2}\right]^{-1}$
The magnetic field in the gas region
$\underline{H}_{1}^{g a s}=\frac{i \alpha H_{o}}{I_{1}(x)} \nabla\left(I_{o}(k r) R_{1}\right)$
The curvature pressure along the gas-liquid interface
$P_{1 s}=\frac{S}{R_{o}^{2}}\left(1-x^{2}\right) R_{1}$
with
$\eta^{2}=k^{2}+\frac{(\sigma+i k U)^{2}}{a^{2} \xi}$
$\xi=1+\frac{\mu H_{o}^{2}}{\rho(\sigma+i k U)^{2}}\left(\frac{(\sigma+i k U)^{2}}{a^{2}}+k^{2}\right)$

Here $\mathrm{x}\left(=\mathrm{k} \mathrm{R}_{\mathrm{o}}\right)$ is the ordinary longitudinal dimensionless wave number, $\mathrm{y}\left(=\eta \mathrm{R}_{\mathrm{o}}\right)$ the compressible longitudinal dimensionless wave number (where $\eta \rightarrow k$ as $a \rightarrow \infty$ ), $I_{0}$ and $K_{o}$ are the modified Bessel functions of the first and second kind of order zero, and $\Omega_{A}=\left(\mu H_{o}^{2} k^{2} / \rho_{o}\right)^{1 / 2}$ is Alfven wave frequency defined in terms of $H_{0}$.

By resorting to the foregoing solutions (12) and (35)-(43) of the basic equations in the unperturbed and perturbed states for compressibility condition (34), the following stability criterion is obtained

$$
\begin{equation*}
(\sigma+i k U)^{2}=\frac{\mu H_{o}^{2}}{\rho_{o} R_{o}^{2}}\left[-x^{2}+\alpha^{2} x y \frac{I_{o}(x) K_{o}^{l}(y)}{I_{o}^{l}(x) K_{o}(y)}\right]-\frac{S}{\rho_{o} R_{o}^{3}}\left(1-x^{2}\right)\left[\frac{y K_{o}^{l}(y)}{K_{o}(y)}\right] \tag{44}
\end{equation*}
$$

## ON PREVIOUS WORKS

The dispersion relation (44) is valid for discussing the MHD stability of compressible hollow jet endowed with surface tension and acted by inertia and electromagnetic forces. This relation related the growth rate $\sigma$ with the wave numbers x and y ; the modified Bessel functions $I_{0}$ and $K_{0}$ of the first and second kinds of order zero and their derivatives, the parameters $\rho_{0}, R_{0}, H_{0}, \mu$ and $S$ of the problem and with the fundamental quantities $\left(\rho R_{o}^{2} / \mu H_{o}^{2}\right)^{\frac{1}{2}}$ and $\left(\rho_{o} R_{o}^{3} / S\right)^{\frac{1}{2}}$ as a unit of time.

The relation (44) is a general relation from which we may recover other reported works as limiting cases.

For an ideal hollow jet endowed with surface tension ( $\mathrm{H}_{\mathrm{o}}=0$ and $a \rightarrow \infty$ ) at rest initially ( $\mathrm{U}=0$ ), we have

$$
\begin{equation*}
\sigma^{2}=\frac{-S}{\rho_{o} R_{o}^{3}}\left(1-x^{2}\right) \frac{x K_{1}(x)}{K_{o}^{l}(x)}, \quad K_{o}^{t}(x)=-K_{1}(x) \tag{45}
\end{equation*}
$$

This relation has been given by Chandrasekhar (1981).
If we assume that the fluid is incompressible $(a \rightarrow \infty)$ and initially the fluid is at rest $(\mathrm{U}=0)$, the dispersion relation (44), yields

$$
\begin{equation*}
\sigma^{2}=\frac{S}{\rho_{o} R_{o}^{3}}\left(1-x^{2}\right]\left[\frac{x K_{1}(x)}{K_{o}(x)}\right]+\frac{\mu H_{o}^{2}}{\rho_{o} R_{o}^{2}}\left[-x^{2}-\alpha^{2} x^{2} \frac{I_{o}(x) K_{1}(x)}{I_{1}(x) K_{o}(x)}\right] \tag{46}
\end{equation*}
$$

This is the magnetohydrodynamic dispersion relation of a hollow jet subjected by the capillary and MHD forces derived and documented by Radwan (1994).

The magnetodynamic dispersion relation of a streaming compressible hollow jet may obtained from equation (44), by just supposing ( $\mathrm{S}=0$ ), in the form

$$
\begin{equation*}
(\sigma+i k U)^{2}=\frac{\mu H_{o}^{2}}{\rho_{o} R_{o}^{2}}\left[-x^{2}+\alpha^{2} x y \frac{I_{o}(x) K_{o}^{t}(y)}{I_{o}^{t}(x) K_{o}(y)}\right] \tag{47}
\end{equation*}
$$

The dispersion relation of a streaming compressible hollow jet subjected by the capillary force could be obtained from (44) as $\left(\mathrm{H}_{0}=0\right)$, in the form

$$
\begin{equation*}
(\sigma+i k U)^{2}=-\frac{S}{\rho_{o} R_{o}^{3}}\left(1-x^{2}\right)\left[\frac{y K_{o}^{t}(y)}{K_{o}(y)}\right] \tag{48}
\end{equation*}
$$

which is valid for all short and long wavelengths.

## DISCUSSION AND RESULTS

In order to investigate the instability and oscillation of the present model we have to write down about the characteristic and behaviour of the modified Bessel functions.
The recurrence relations of the modified Bessel functions(cf. Abramowitz and Stegun (1970) are given by
$2 F_{m}^{\iota}(x)=F_{m-1}(x)+F_{m+1}(x)$
where $F_{m}^{l}(x)$ stands for $I_{m}^{l}(x)$ and $-K_{m}^{l}(x)$ while $\mathrm{F}_{\mathrm{m}}(\mathrm{x})$ stands for $\mathrm{I}_{\mathrm{m}}(\mathrm{x})$ and $\mathrm{K}_{\mathrm{m}}(\mathrm{x})$. By the use of relations (49) and the fact that $\mathrm{I}_{0}(\mathrm{x})$ is positive definite and monotonic increasing while $K_{0}(x)$ is monotonic decreasing but never negative for non-zero real value of $x$, we have

$$
\begin{gather*}
I_{o}(x)>0, K_{o}(x)>0, x \neq 0  \tag{50}\\
I_{0}^{l}(x)>0, K_{0}^{t}(x)<0 \tag{51}
\end{gather*}
$$

Based on the inequalities (50) and (51), we get
$\frac{x K_{o}^{t}(x)}{K_{o}(x)}<0$
$\frac{x^{2} I_{o}(x) K_{o}^{i}(x)}{I_{o}^{\iota}(x) K_{o}(x)}<0$
By utilizing (52) for (48) as ( $\mathrm{U}=0$ ), we see that

$$
\begin{array}{ll}
\frac{\sigma^{2}}{\left(S / \rho_{o} R_{o}^{3}\right)^{1 / 2}} \leq 0, & \text { as } 1 \leq x<\infty \\
\frac{\sigma^{2}}{\left(S / \rho_{o} R_{o}^{3}\right)^{1 / 2}}>0, & \text { as } 0<x<1 \tag{55}
\end{array}
$$

This means that the cylindrical hollow jet is capillary unstable only for small domain of wave number while it is stable in all other domains.

From the view point of the inequality (53) the dispersion relation (47) reveals that both the magnetic fields pervaded in the gas and liquid regions have stabilizing effects. The stabilizing effect of the magnetic field in the gas region is valid for all short and long wavelengths. The analytical discussions indicate that the streaming has strong destabilizing effect.
Here we seek very important task concerning the effect of the compressibility on the stability of the hollow jet model which is in hand .
In the earlier studies of incompressible hollow jet by several authors (Chandrasekhar (1981), Drazin \& Reid (1980), Cheng (1985), Kendall (1986), Radwan (1991).... etc.) that give rise
to the classical dispersion relation presuppose that the fluid moves incompressible i.e., that the divergence of the fluid velocity vanishes. that the compressibility has a stabilizing tendency. See also Chen (2003) and Shkadov\& Sisoev (1996).

In reality the compressibility effects need careful treatment in each case of different models. Here we found that the incompressible fluid results are obtained as $a^{2} \rightarrow \infty$ ( $a$ is sound speed in the fluid). However for finite values of a (i.e. the fluid is compressible) it is expected that the growth rate values are larger than in the case of incompressible fluid. The unstable region of a compressible fluid is much larger than that of an incompressible fluid in the wave number domain of instability. This shows that, in our case of a hollow jet that the compressibility has a strong destabilizing tendency for all ( short and long ) wavelengths.
Any how such discussion and results could be judged and identified via the numerical analysis of the general dispersion relation (44) for different values of the different factors of the problem.

## NUMERICAL ANALYSIS

The dispersion relation (44) has been discussed numerically for all short and long wavelengths in which the dimensionless wave number is taken to be $0<\mathrm{x} \leq 3$ and the corresponding values of $\sigma$ or $\omega$ in the normal unit $\sqrt{\left(S / \rho R_{o}^{3}\right)}$ where ( $\omega / 2 \pi$ is the frequency of oscillation ) are determined. This has been performed for various values of $\left(H_{o} / H_{s}\right)$ and $\alpha$. Then for every couple values of $\left(\left(H_{o} / H_{s}\right), \alpha\right)$, different values of $a$ is considered where $H_{s}=\sqrt{\left(S / \mu R_{o}\right)}$.

The numerical data are collected in tables, see tables (1)-(5) and presented in graphs, see figures (1)-(5). There are many features of interest in these tables and figures.

Corresponding to $\left(\left(H_{o} / H_{s}\right), \alpha\right)=(0,0.1)$ as $a=1,5,10,20$ and 30 ; it is found that the unstable domains are $0<x<1.36928,0<x<1.133103,0<x<1.085419,0<x<$ 1.050069 and $0<x<1.04138$, while the neighboring stable domains are given by 1.36928 $<\mathrm{x}<\infty$, $1.133103<\mathrm{x}<\infty, 1.085419<\mathrm{x}<\infty, 1.050069<\mathrm{x}<\infty$ and $1.04138<\mathrm{x}<\infty$. The critical points at which the transition from stable states to those of instability are occurred at $\mathrm{x}_{\mathrm{c}}=1.36928,1.133103,1.085419,1.050069$ and 1.04138 respectively. See figure ( 1 ) and table ( 1 ).
Corresponding to $\left(\left(H_{o} / H_{s}\right), \alpha\right)=(0.1,1)$ as $a=1,5,10,20$ and 30 ; it is found that the unstable domains are $0<\mathrm{x}<1.353,0<\mathrm{x}<1.12614,0<\mathrm{x}<1.07631,0<\mathrm{x}<1.04187$ and $0<x<1.03322$, while the neighboring stable domains are given by $1.353<x<\infty$, $1.12614<\mathrm{x}<\infty, 1.07631<\mathrm{x}<\infty, 1.04187<\mathrm{x}<\infty$ and $1.03322<\mathrm{x}<\infty$. The critical points at which the transition from stable states to those of instability are occurred at $x_{c}=$ $1.353,1.12614,1.07631,1.04187$ and 1.03322 respectively. See figure (2) and table (2).

Corresponding to $\left(\left(H_{o} / H_{s}\right), \alpha\right)=(0.3,1)$ as $a=1,5,10,20$ and 30 ; it is found that the model at hand is completely stable for all values of a for all short and long wavelengths. This means that the stabilizing effect of the magnetic field is predominating the compressibility destabilizing influence, and there is no any unstable state any more. See figure (3) and table (3).

Corresponding to $\left(\left(H_{o} / H_{s}\right), \alpha\right)=(0.1,2)$ as $a=1,5,10,20$ and 30 ; it is found that the unstable domains are given by $0<x<1.84733,0<x<1.334,0<x<1.272,0<x<$ 1.149 and $0<x<1.1036$, while the neighboring stable domains are given by $1.84733<\mathrm{x}<$ $\infty, 1.334<x<\infty, 1.272<x<\infty, 1.149<x<\infty$ and $1.1036<x<\infty$. The critical points at which the transition from stable states to those of instability are occurred at $\mathrm{x}_{\mathrm{c}}=1.84733$, $1.334,1.272,1.149$ and 1.1036 respectively. See figure (4) and table (4).

Corresponding to $\left(\left(H_{o} / H_{s}\right), \alpha\right)=(0.1,3)$ as $a=1,5,10,20$ and 30 ; it is found tha the unstable domains are $0<x<2.6997,0<x<1.75392,0<x<1.51354,0<x<1.336269$ and $0<x<1.28833$, while the neighboring stable domains are given by $2.6997<x<\infty$, $1.75392<\mathrm{x}<\infty, 1.51354<\mathrm{x}<\infty, 1.336269<\mathrm{x}<\infty$ and $1.28833<\mathrm{x}<\infty$. The critical points at which the transition from stable states to those of instability are occurred at $\mathrm{x}_{\mathrm{c}}=$ $2.6997,1.72392,1.51354,1.336269$ and 1.28833 respectively. See figure (5) and table (5) .

From the foregoing discussion we may conclude the following results.
1- The unstable domains are decreasing with increasing the values of compressibility parameter a. This means that the analytic result that the compressibility is stabilizing and verified numerically.

2- The magnetic field parameter $\alpha$ is stabilizing.
3- The magnetic field is strong stabilizing whatever its smallest value.
4- The capillary force destabilizing effect may be suppressed by the stabilizing effect of the magnetic field and compressibility, and moreover stability sets in.
