ABSTRACT

Organic farming has gained ground worldwide and has expanded in recent years due to environmental, economic, and social concerns. In Egypt, up to 2.23 % of the agricultural area is managed organically. The transition from conventional to organic farming is accompanied by changes in an array of soil properties and processes that affect soil fertility. These changes in soil properties under Egyptian condition are not well documented. Therefore, the present study was carried out to study the comparative effects of organic and conventional farming systems on some soil chemical indicators under Egyptian condition.

Surface soil samples (0-30 cm) were collected from eight field pairs (organic field and its conventional counterpart) to represent organic farms in three locations (Fayoum (Tubhar village), Bilbeis city (SEKEM Organic Farm) and Salhyia city). The organic fields were in organic practice for 4, 6, and 10 years (Fayoum samples), 20 and 30 years (Sharkyia samples), 8, 10 and 12 years (Ismailia samples) since certification. The studied soil chemical indicators include soil organic carbon, T-N, pH, EC, CEC, exchangeable cations, and available N, P, K, Fe, Mn, Zn and Cu.

Soil organic carbon, T-N, CEC, and available N, P, K, Fe, and Mn were significantly higher in the organic system than in the conventional system. Also organically managed soils showed significantly better soil nutritional status regardless the periods of organic farming practice. On the other hand, soil pH, EC, available Cu and Zn were higher in the conventional system than in the organic system.

Keywords: organic farming, soil quality indicators, available nutrients and soil chemical properties

INTRODUCTION

Organic farming has gained ground worldwide and has expanded in recent years due to environmental, economic, and social concerns (Gasparatos *et al*, 2011). It has been proposed as an alternative agricultural system to solve the environmental problems arising from conventional farming management, such as pesticide application, excessive inputs of synthetic chemical fertilizers, soil degradation, and the presence of pesticide residues in food (Stockdale *et al.*, 2001).

In Egypt, up to 2.23 % of the agricultural area is managed organically according to European Union Regulation (Willer and Klicher, 2012). The transition from conventional to organic farming is accompanied by changes in an array of soil properties and processes that affect soil fertility (Clark *et al.*,

1998; Herencia *et al.*, 2008). A growing number of studies showed that organic farming leads to higher quality soil and more soil biological activity than conventional farming. The impact of organic and conventional farming systems on soil showed that the organically managed soils contained higher levels of organic carbon (Mazoncini *et al.*, 2010; Omar *et al.*, 2010 and Wang *et al.*, 2012), pH, total nitrogen, CEC (Gadja and Martyniuk, 2005; Melero *et al.*, 2006; Araujo *et al.*, 2009), soluble phosphorus and potassium (Clark *et al.*, 1998), and soil microbial growth and enzyme activities (Liu *et al.*, 2007; Okur *et al.*, 2009; Wang *et al.*, 2012). However, some authors reported some different trends (Marinari *et al.*, 2006; Hathaway *et al.*, 2011; Gasparatos *et al.*, 2011).

Soil quality depends on the physical, chemical, biological, and biochemical properties of the soil, changes in these properties must be taken into account in assessing changes in soil quality (Babu *et al.*, 2010). The comparison of organic with conventional systems is complex and difficult (Watson *et al.*, 2008). The objective of the present study was conducted to compare the impacts of organic and conventional farming systems on some chemical and fertility indicators of soil under Egyptian conditions.

MATERIALS AND METHODS

Soil samples were collected from eight field pairs representing three locations in three governorates. In Fayoum governorate, three field pairs were selected from Fayoum organic farm, Tubhar village. 29°18' N and 30°24' E. Three organic fields which were under organic farming system for 4, 6 and 10 years and three adjacent fields representing the conventional fields. In Sharkya governorate, two different locations were selected, SEKEM Organic Farm, Bilbeis city, 30°09' N, 31°25' E, and Salhyia private organic farm, Salhyia El Gededdah city, 30°38' N, 31°56' E. Two organic fields which were under organic farming for 20 and 30 years as well as two adjacent conventional fields were sampled from SEKEM organic farm, and three organic fields which were under organic farming for 8, 10 and 12 years and three adjacent conventional fields were sampled from Salhyia farm.

Soils were sampled first at 3/2012 and second at 3/2013 except those of Fayoum location which were sampled once, at 8/2012. Five soil sample replicates were taken per field, each replicate was a composite sample of three soil samples taken at random using an auger to a depth of 30 cm. Soil samples were air dried and ground using a wooden hammer and sieved through a 2 mm-mesh screen prior to the following chemical analyses.

Organic carbon was measured according to Walkley and Black, total nitrogen (T-N) by the Kjeldahl method (Page *et al.*, 1982). Soil pH was measured in 1: 2.5 soil water suspensions, electrical conductivity (EC) was determined in 1:2.5 soil water ratio extract (Jackson, 1973). Available phosphorus was extracted with 0.50 M NaHCO₃ solution according to Olsen *et al.* (Black, 1965) and determined according to Watanabe and Olsen procedure (Page *et al.*, 1982). Available potassium was extracted with ammonium acetate solution and determined photometrically (Jackson, 1973).

Available micronutrient, (Fe, Mn, Zn, and Cu) were extracted according to Lindsay and Norvel method(1978) and determined using atomic absorption spectrophotometry (Unicam 767). Exchangeable cations and the cation exchange capacity of soil (CEC) were determined using an ammonium acetate method (Page et al., 1982).

Statistical analysis:

Data were analyzed using a completely randomized design using Costat (Costat Statistical Software, 2003) and analysis of variance was used to determine significant differences among sampling time, period of organic certification, and farming system after transformation to normalize data and equalize variance as required. Significance level was set at ($P < 0.05$). Comparison between means was made with the Duncan's multiple range (DMR) test. When treatment x year interactions was not significant, data were combined across years. Statistical analysis was made for each location separately.

RESULTS AND DISCUSSION

Soil Organic Carbon, SOC

Soil Organic Carbon SOC have a beneficial impact on soil quality, enhancing soil structure and fertility, increasing water infiltration and storage (Magdolf, 2004). Analysis of variance indicated that SOC was significantly affected by farming system as well as the period of organic farming practice in the three studied locations. In Fayoum location (Fig 1), the SOC content increased significantly from 10.89, 12.00 and 13.40 g/kg in conventionally managed soils to 11.77, 12.99 and 15.69 g/kg in soils that organically managed for 4, 6 and 8 years which represented 8.0, 8.2 and 18.9% increases, respectively (Table 1). In SEKEM samples, the corresponding increases were from 7.69 and 11.85 g/kg-1 in conventionally managed soils to 10.93 and 13.87 g/kg-1 % increases in organically managed soils for 10 and 20 and 30 years which represent 42.13 and 17.05% increases, respectively. In Salhyia samples, the SOC content followed the same trend as that of Fayoum and SEKEM samples, being higher in organically than conventionally managed soils by 14.4, 13.6, and 29.8% after 8, 10, and 12 years of organic farming management, respectively. A higher concentration of SOC is often considered to be an inevitable result of conversion to organic farming system (Stockdale *et al.*, 2001). These results are in agreement with those reported by many authors who found a higher concentration of SOC in organically managed soils (Mader *et al.*, 2002; Pulleman *et al.*, 2003). In Egypt, Omar et al. (2010) reported a comparable results, He found that total organic matter had increased in organically managed soils with the increase in organic farming period.

Fig. 1. Soil organic carbon (a), Total-N (b) and pH(c) as affected by Farming system (CON & ORG) and period of organic farming at the three locations (Fayoum, SEKEM & Salhyia).

Total Nitrogen, T-N

Analysis of variance summary (Table 1) indicated that soil total nitrogen (T-N) followed almost the same trend as that of SOC, significantly affected by farming system and the period of organic farming practice and being higher in organically managed soils than in conventionally managed ones. The similar pattern was observed between SOC and T-N is to be expected (Fig 1), since the total nitrogen content of a soil is primarily a component of the soil's organic matter content.

Table 1. Analysis of variance for some soil properties as affected by season, period of organic farming (P), and farming system in different soil locations.

t-

***, **, *** Significant at the 0.05, 0.01, and 0.001 probability levels, respectively,
NS = not significant.**

The percent increases in T-N concentration in Fayoum organically managed soils over conventionally managed ones were 5.7, 9.4, and 9.2 % due to 4, 6, and 10 years of organic farming, respectively. The corresponding percentages for SEKEM samples were 22.10 and 11.16 % due to 20 and 30 years of organic farming, respectively. While the percent increases for Salhyia were 29.60, 29.28, and 23.64 % due to 8, 10, and 12 years of organic farming, respectively. The higher levels of T-N are also observed in all of the organic soil with various plants by Wang *et al.* (2012). To some extent, higher C and N in organic farming system suggest that soil quality in organic farms have been improved (Wang *et al.*, 2012).

Soil pH

Soil pH values were significantly affected by farming system as well as period of organic farming (Table 1). All the soils of both conventional and organic fields are alkaline in reaction (Fig 1). The pH values ranged from 8.01 to 8.24 in the organic fields and from 8.08 to 8.78 in the conventional fields. Organically managed soils exhibited a slight but significant decline in pH values compared with conventionally managed counterparts. The overall means of soil pH indicated that the pH values decreased from 8.15, 8.29 and 8.61 to 8.06, 8.18 and 8.23 in Fayoum, SEKEM and Salhyia samples, respectively. The decrease in soil pH in organically managed soils might be due to the formation of organic acids during decomposition and mineralization of organic manure and compost. Omar (2010) found that compost addition decreased soil pH of Fayoum and SEKEM samples with time in the batch and column experiments.

Soil Salinity, EC

Analysis of variance data (Table 1) show that soil EC was significantly affected by farming system as well as period of organic farming. In general, EC value in each organically managed field was significantly less than its value in the conventionally managed counterpart, except one field in Fayoum samples. In Fayoum samples, the EC values ranged from 0.67 to 1.30 dSm⁻¹ in the organic fields and from 0.77 to 2.08 dSm⁻¹ in the conventional fields. The corresponding ranges for Salhyia location were from 0.41 to 0.84 dSm⁻¹ and from 0.67 to 1.07 dSm⁻¹, respectively. In SEKM location, EC values followed the same trend, being significantly higher in conventionally managed soils than in organically managed ones. An exceptionally higher EC values were recorded in the 30 years of organic farming field and its conventional counterpart in SEKM due to the high salinity of the applied irrigation water in these fields.

The increase of the EC in the conventionally managed soils could be due to the higher input of salts in the form of chemical fertilizers and/or pesticides (Gasparatos *et al.*, 2011). The relatively low EC levels in the organically managed soils indicate that the use of composts has not resulted in increased salinity (Clark *et al.*, 1998). The results of the present study are in agreement with those of Stark (2005), Rahman *et al.* (2011), and Gasparatos *et al.* (2011).

Cation Exchange Capacity (CEC) and Exchangeable Cations

Cation Exchange Capacity (CEC) was significantly affected by organic farming system and the period of its management (Table 1). Organically managed soils had higher CEC values than their conventionally managed counterparts, However, the differences in CEC values between organic and conventional farming systems did not reach the significant level (at 0.05 significant level) until 6 years of organic farming (Table 1). On the other hand, there are significant increases between organic and conventional systems at higher periods of organic farming (8-30 years). The higher CEC in organic soil samples could be attributed to its greater organic C. Huang *et al.* (2002) found that cation exchange capacity is highly related to the amount of organic matter.

Exchangeable Ca almost followed the same trend as that of CEC (Fig 2). This is not surprising since EX-Ca is the dominant cation on the exchange complex of the studied soils. On the other hand, exchangeable magnesium, EX-Mg, did not follow a consistent trend among the three locations, being significantly higher in organically managed soils in Fayoum and Salhyia locations, while the reverse trend was found in SEKEM location.

Exchangeable sodium (Ex-Na) was significantly lower in organically than conventionally managed soils in all locations, except the 4 year organically managed soil in Fayoum location, which showed a reverse trend (Fig 3). On the other hand, conventionally managed soils had higher Ex-K than their organically managed counterparts which referred to inorganic addition of K fertilizers.

Availability of macronutrients (N, P and K)

Organically managed soils contained higher levels of available N than the conventionally managed ones (Fig 4). In Fayoum location, the concentration of available N increased by about 11.0, 4.0, and 37.0 % in soils that managed organically as compared to conventional ones for 4, 6, and 10 years, respectively. The corresponding increases in SEKEM location were 45.0 and 12.0 % in soils managed organically for 20 and 30 years, respectively. While the corresponding increases in Salhyia location was 11.0, 26.0, and 37.0 % in soil that organically managed for 8, 10, and 12 years, respectively. The increase in available N in organically managed soils over conventionally managed ones could be due to the higher biological activity which accelerates the mineralize organically bound N to inorganic form (Bellakki and Badanur, 1997). These results are in agreement with those of Lehocka *et al.* (2008), Bhogal *et al.* (2008), Meleró *et al.* (2006), and Ge *et al.* (2011).

Statistical analysis revealed that available P was significantly increased progressively with increasing the period of organic farming within each location (Table 2). Organically managed soils had higher P content than conventionally managed soils. Available P concentration ranged from 8.1 to 17.8 with an average of 12.8 mg/kg in conventionally managed soils and from 11.3 to 24.0 with an average of 19.7 mg/kg in organically managed soils in Fayoum. In Salhyia location, P concentration ranged from 15.0 to 30.7 with an average of 25.4 mg/kg in conventionally managed soils and from 20.0 to 50.2 with an average of 28.0 mg/kg in organically managed soils. In SEKEM location, P concentration ranged from 23.9 to 30.7 with an average of 27.3 mg/kg in conventionally managed soils and from 34.4 to 53.4 with an average of 43.9 mg/kg in organically managed soils. The observed increase in available P levels appeared to be the direct result of inputs. The greatest amounts of P were applied to the organic systems as constituents of the applied composts and rock phosphate. These results are in agreement with those reported by Clark *et al.* (1998), Marinari *et al.* (2006), Herencia *et al.* (2008), and Gasparatos *et al.* (2011).

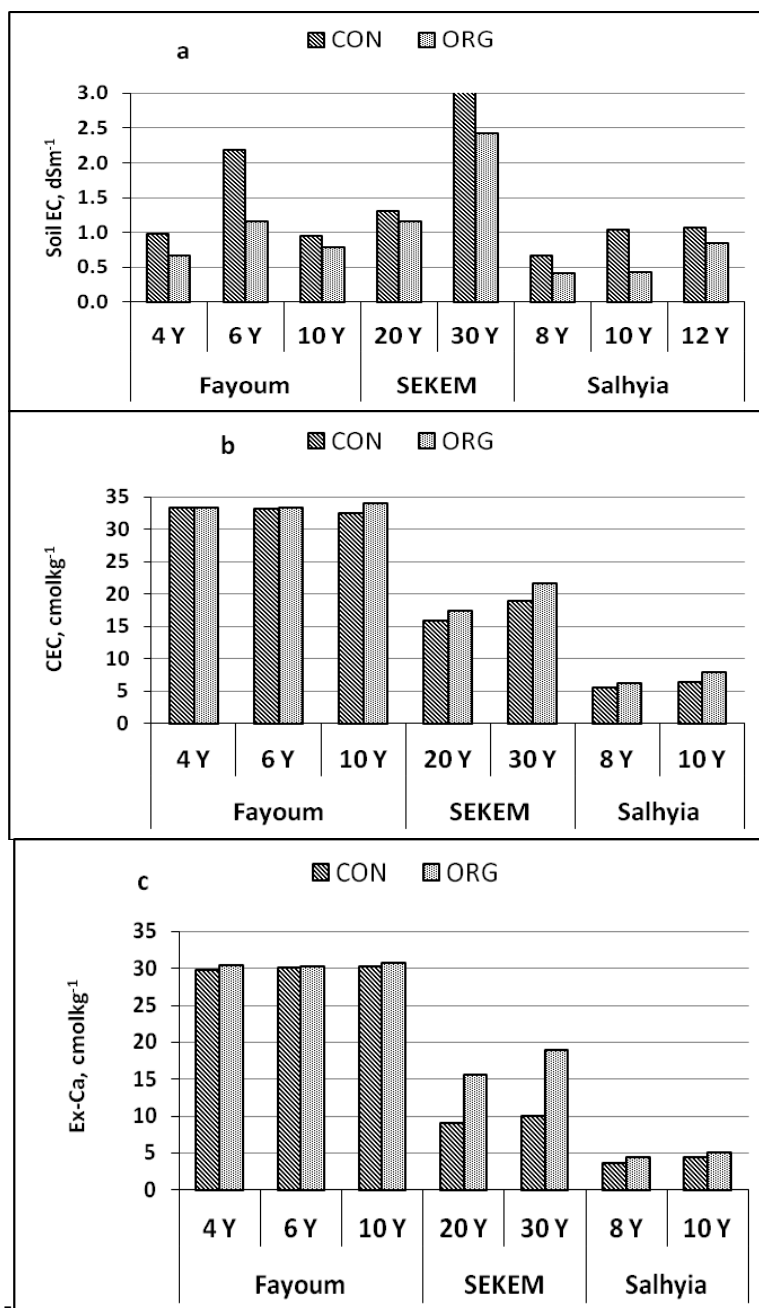

Fig. 2. . Soil EC(a), CEC(b) and Exchangeable-Ca(c) as affected by Farming system (CON & ORG) and period of organic farming at the three locations (Fayoum, SEKEM & Salhyia).

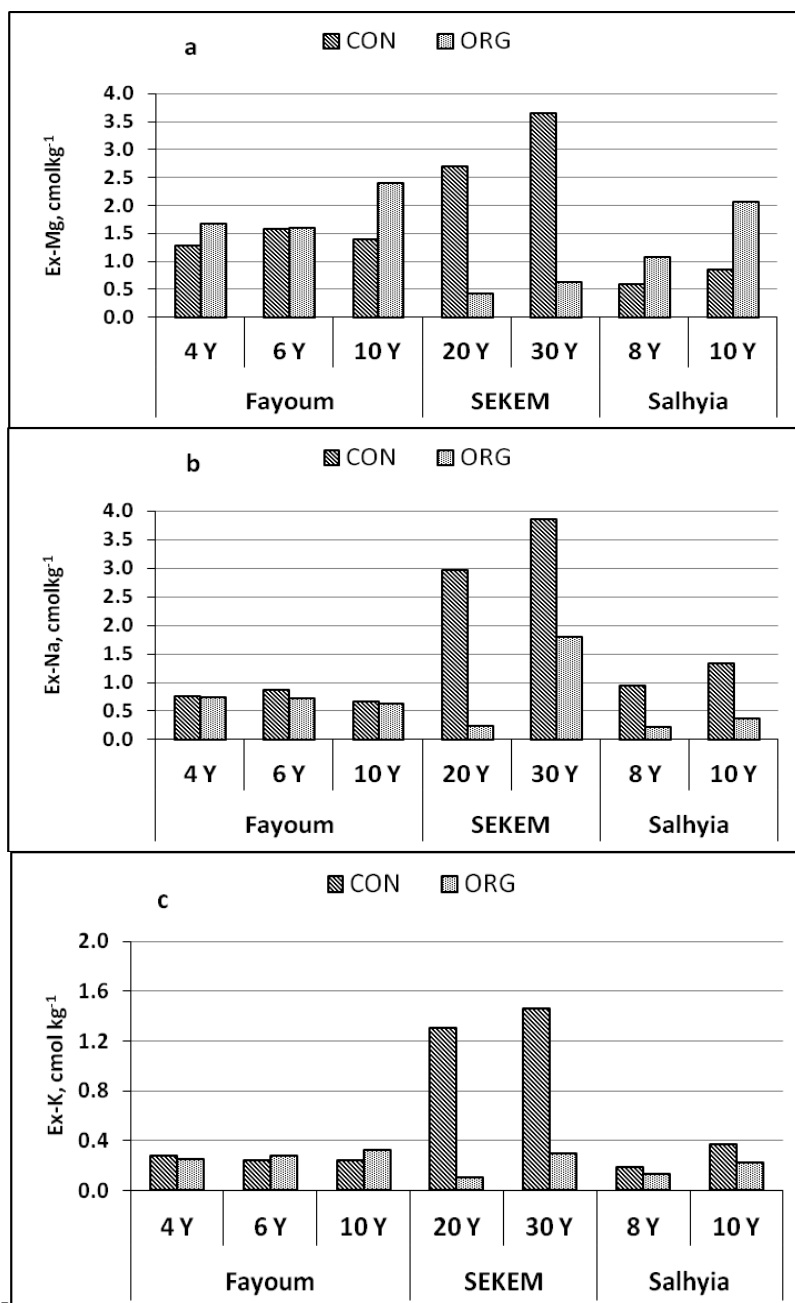

Fig. 3. Exchangeable-Mg(a), Na (b) and K (c) as affected by Farming system (CON & ORG) and period of organic farming at the three locations (Fayoum, SEKEM & Salhyia).

Fig. 4. Available-N (a), P (b) and K (c) as affected by Farming system (CON & ORG) and period of organic farming at the three locations (Fayoum, SEKEM & Salhyia).

Available K concentration did not follow a consistent trend among the three locations (Fig 4). In Fayoum location, K concentration was significantly higher in organic fields than conventional fields. However, in SEKEM and Salhyia locations, K concentration showed a reverse trend being significantly higher in conventional fields of SEKEM location and consistently higher in conventional fields of Salhyia location. The contrast results regarding the behavior of available K in organic compared to conventional farming system were also reported by many authors. Clark *et al.* (1998), Edmeades (2003), Herencia *et al.* (2008), and Chhotaray *et al.* (2010) found that organically managed soils contained more available K than conventionally ones. On the other hand, Nguyen *et al.* (1995), Gosling *et al.* (2006), Abu-Zahra and Thboub (2008), and Gasparatos *et al.* (2011) found that organically managed soils contained less available K than conventionally ones and claimed that organic farming is exploiting reserves of K that built up by fertilizer addition prior to organic management. In some organic farms the use of the powder of the K-bearing minerals (feldspar – biotite etc.) may increase the concentration of the available-K (Mikkelsen, 2008).

Availability of micronutrients (Fe, Mn, Cu and Zn)

Available iron was significantly affected by organic farming system and period of organic farming in Fayoum and SEKEM locations. While in Salhyia location, differences in available- Fe between conventional and organic farming systems did not reach the significant level (Table 2). However, in all locations, the organically managed soils contained higher available Fe and Mn than the conventionally ones (Table 11). In contrast, the available Cu and Zn were notably lower in organically managed soils than in conventionally managed ones (Fig 5)).

The above mentioned results regarding available micronutrients are in agreement with those reported by several authors. Herencia *et al.* (2008) found that organically managed soils had more Fe and Mn than the conventionally ones, they reported that the slightly higher levels of these micronutrients could be due to the formation of soluble organic complexes with the organic materials. The lower concentration of Cu and Zn in organically managed soils compared to conventionally managed soils could be due to the application of agrochemicals, such as pesticides (copper containing fungicides) and synthetic fertilizers (containing both Cu and Zn), in the conventional farming system (Gasparatos *et al.* 2011).

شهدت الزراعة العضوية فى السنوات الاخيرة انتشارا واسعا سواء فى مصر او فى دول العالم نتيجة لاعتبارات بيئية واقتصادية واجتماعية. ويصاحب التحول من الزراعة التقليدية الى الزراعة العضوية تغييرات فى مجموعة من صفات التربة والعمليات الحيوية التى تحدث بها مما يؤثر على خصوبة التربة. وتهدف هذه الدراسة الى مقارنة تأثير كل من الزراعة العضوية والتقليدية على الصفات الكيميائية والخصوبية للتربة تحت الظروف المصرية. شملت الصفات الكيميائية التى تمت دراستها رقم حموضة التربة، التوصيل الكهربى لمستخلص التربة، محتوى التربة من الكربون العضوى، النيتروجين الكلى، السعة التبادلية الكاتيونية ومحتوى التربة من العناصر الميسرة الكبرى والصغرى.

تم اخذ عينات تربة سطحية (0-30 سم) ممثلة لعدد من المزارع العضوية ومثيلاتها من المزارع التقليدية من ثلاثة مواقع مختلفة. من مزرعة الفيوم العضوية بمحافظة الفيوم تم اخذ عينات من ثلاثة حقول تحت الزراعة العضوية لمدة 4, 6 و 10 اعوام وثلاثة حقول مجاورة تمثل الزراعة التقليدية. ومن مزرعة سيكام بمحافظة الشرقية تم اخذ عينات تربة تمثل حقلين تحت الزراعة العضوية لمدة 20 و 30 عاما بالاضافة الى حقلين مجاورين يمثلان الزراعة التقليدية. ومن مزرعة عضوية خاصة بمدينة الصالحية بمحافظة الشرقية تم اخذ عينات ممثلة لثلاثة حقول تحت الزراعة العضوية لمدة 8, 10 و 12 عاما بالاضافة الى ثلاثة حقول مجاورة تمثل الزراعة التقليدية. وتشير النتائج المتحصل عليها الى ان الاراضى تحت نظام الزراعة العضوية قد أظهرت تحسنا معنويا فى الصفات الكيميائية والخصوبية مقارنة بالاراضى تحت نظام الزراعة التقليدية وان هذا التحسن قد تأكد وازداد بزيادة فترة الزراعة العضوية.
