Plant Protection Department, Faculty of Agriculture, Assiut University, Assiut, Egypt.

ABSTRACT

Three levels (5, 10 and 15 gm) of ten powders and three concentrations (0.5%, 1% and 2%) of six liquids were used with mulberry leaves for feeding of 4th and 5th instars of local and imported silkworm. Their effects were studied on total soluble solids % (T.S.S.%) and total counts of haemocytes (T.C.H.)/mm³ haemolymph of 5th instar of silkworm larvae. The used tested powders were: glucose, fructose, sucrose, white or brown, soya, skim milk and their mixture (1:1), soya plus pollen (1:1), yeast and foliar fertilizer, while liquid treatments were: bee honey from Assiut or Sohag, chloral hydrate, foliar fertilizer, potassium iodide and ammonium chloride. Different responses in (T.S.S.%) and (T.C.H.) were noticed between local and imported silkworm, with respect to the effect of tested powder and liquid treatments. In powder treatments, maximum increment in (T.S.S.%) and (T.C.H.), in larval haemolymph of local silkworm was observed in skim milk treatment or its mixture with soya, while less effect was noticed in foliar fertilizer treatment. Sugars and soya plus skim milk showed maximum increment of (T.S.S.%) and (T.C.H.) in imported silkworm. T.S.S.% and T.C.H. in powder or liquid treatments were less in imported silkworm as compared with local ones. Liquid treatments with honey, ammonium chloride and chloral hydrate showed positive effect on (T.S.S.%) and (T.C.H./mm³ haemolymph) in local and imported silkworm. Detailed statistical analysis of obtained data was conducted and differences between strains and treatments were discussed.

INTRODUCTION

Insect haemolymph contains haemocytes suspended in plasma. Haemocytes have essential roles in numerous physiological activities (Wigglesworth, 1959). This fluid reflects physiological or pathological condition of the insect (Kostecki, 1965).

Effects of different factors or treatments on the larval haemolymph of silkworms were studied by many researchers: Radwan, 1978; El-Deeb, 1981; Horrie and Watanbe, 1983; Salem *et al.*, 1985a,b; Abd El-Naby, 1988; Reddy *et al.*, 1991; Thyagaraja *et al.*, 1991; Ashour, 1997; Eid *et al.*, 1999 and Abdellah, 2007.

This work aims to study the effects of ten powder and six liquid treatments of mulberry leaves on total soluble solids (%), and total counts of haemocytes/mm³ in 5th instar larval haemolymph of local and imported silkworm.

MATERIALS AND METHODS

Ten powder treatments were used with mulberry leaves in feeding of 4th and 5th instars of silkworm. They were: glucose, fructose, white or brown sucrose, soya, skim milk and their mixture (1:1), soya plus pollen (1:1), yeast and foliar fertilizer. Three levels, 5, 10 and 15 gm, were used for each treatment.

Six liquid treatments were used with mulberry leaves for feeding of 4th and 5th instars of silkworm. They were: bee honey from Assiut or Sohag, chloral hydrate, potassium iodide, ammonium chloride, and foliar fertilizer. Three concentrations, 0.5%, 1% and 2%, were used for each treatment.

Every tested powder or liquid was replicated three times in three carton boxes, each contain 40 larvae. Feeding with treated leaves was conducted four times/day. Control larvae were fed with untreated mulberry leaves.

A simple method adopted by (Hussein, 1978) using hand refractometer was used for determination of total soluble solids (%) in 5th instar larval haemolymph. Total counts of haemocytes in larval haemolymph was conducted as described by (Predtetschensky *et al.*, 1950).

RESULTS AND DISCUSSION

Data of the effect of tested powder treatments and their (percentages over control) on (T.S.S.%) in larval haemolymph of local and imported silkworm, are summarized in Table (1).

Maximum mean (T.S.S.%) in larval haemolymph of local silkworm was 11.97%, or (39.186%), in soya-plus skim milk (5 gm) treatment. T.S.S.% were more in all treatments, as compared with control.

Maximum mean (T.S.S.%) in imported silkworm was 13.73% (or 56.023%) in brown sucrose (10 gm) treatment. T.S.S.% were more than control in all treatments, except foliar fertilizer treatment.

Highly significant differences in T.S.S.% were detected between all treated powder treatments and control, except soya + pollen and foliar fertilizer treatments. No significant differences between tested sugars, and brown sucrose was superior.

T.S.S.% in two strains together was significantly more than control in the following powder treatments: white, or brown sucrose, fructose, glucose and soya.

Data in Table (2) show the effect of examined liquid treatments on mean (T.S.S.%) in larval haemolymph of local and imported silkworm and their percentages over control.

Maximum mean of (T.S.S.%) in haemolymph of local silkworm was 11.15% or (29.651%) and 10.62%, or (23.488%), in Sohag and Assiut bee honey (0.5%) treatments. Figures of (T.S.S.%) in liquid treatment were less than those in powder treatments of local silkworm.

Maximum mean of (T.S.S.%) in haemolymph of imported silkworm was 10.21%, or (16.023%), and 10.18%, or (15.682%), in ammonium chloride (1%) and chloral hydrate (1%) treatments. Figures of (T.S.S.%) in liquid treatments were less than powder treatments, in both of local or imported silkworm.

No significant differences in T.S.S.% in liquid treatments, were noticed between tested treatments, and between them and control.

Data in Table (3) show the effect of powder treatments on total counts of haemocytes (T.C.H.)/mm³ of 5th larval instar haemolymph of local and imported silkworm and their percentages over control.

Maximum mean number of haemocytes was found in soya plus skim milk treatment (15 and 5 gm). The same was noticed with respect to (T.S.S.%) in Table (1). The following treatments were less than control: glucose, fructose, brown sugar, yeast and foliar fertilizer (Table 3).

Maximum mean number of haemocytes was noticed in glucose (15 gm) treatment. T.C.H./mm³ haemolymph in imported silkworm were less than those in local silkworm.

No significant differences in T.C.H. were noticed between all powder treatments and control, except in soya-plus skim milk treatment, in which T.C.H. was significantly increased over control. No significant differences in T.C.H. between different tested powder levels inside treatments.

Table 1: Effect of powder treatments on mean T.S.S.%, larval haemolymph, and (percentages over control), of local and imported silk worm.

Means followed by the same letter are not significantly different at 5% level of significance.

Data in Table (4) show the effect of tested liquid treatments on (T.C.H.) in local and imported silkworm, and calculated percentages over control readings.

Maximum mean of (T.C.H.) in local silkworm was observed in chloral hydrate (0.5%) treatment. Sohag honey and ammonium chloride treatments were less than control readings, while Assiut honey, foliar fertilizer, potassium iodide and chloral hydrate readings, were more than control.

Maximum mean of (T.C.H.) in imported silkworm was found in ammonium chloride (0.5% and 2%) treatments. T.C.H. in imported silkworm were less than those of local silkworm, in both of powder or liquid treatments.

No significant differences in T.C.H. were found between liquid treatments and control. Significant differences was noticed between T.C.H. in control larvae of local and imported silkworm.

In powder treatments, highly significant differences were detected between strains and between and within treatments, while in liquid treatments, highly significant differences were noticed between strains, and not between or within treatments.

تم إختبار ثلاثة جرعات (5، 10 و 15 جم) من عشرة مساحيق وثلاثة تركيزات (0.5%، 1% و 2%) من ستة سوائل وذلك بإضافتها لأوراق التوت المستخدمة لتغذية العمرين الرابع والخامس لدودة القز المحلية والمستوردة وذلك من ناحية تأثيرها على النسبة المئوية للمواد الصلبة الكلية والعدد الكلى لخلايا الدم في ميموليمف ليرقات العمر الخامس لدودة القز. كانت المساحيق المختبرة هي: جلوكوز، فركتوز، سكروز أبيض أو بنى، صويا، لبن فرز ومخلوطه مع الصويا (1:1)، صويا + حبوب لفاح (1:1)، خميرة وسماد ورقى، بينما كانت السوائل المختبرة كما يلي: عسل النحل من أسيوط أو سوهاج، كلورال هيدرات، سماد ورقى، يوديد بوتاسيوم وكلوريد أمونيوم. لوحظت إستجابة مختلفة فى محتوى المواد الصلبة الكلية (%) والعدد الكلى لخلايا الدم ما بين السلالة المحلية والمستوردة من دودة القز، وذلك بعد المعاملة بالمساحيق والسوائل المستخدمة. بالنسبة لمعاملات المساحيق كانت أعلى زيادة لصفات الهيموليمف المدروسة فى السلالة المحلية وذلك فى معاملة لبن الفرز وكذلك مخلوطه مع الصويا، بينما لوحظ أقل تأثير فى معاملة السماد الورقى. أظهرت السكريات المستخدمة والصويا مع لبن الفرز أعلى تأثير بالنسبة للسلالة المستوردة. كانت نسبة المواد الصلبة الذاتية الكلية وأعداد خلايا الدم فى معاملات المساحيق أو السوائل أقل فى السلالة المستوردة عن السلالة المحلية. كان لمعاملات العسل وكلوريد الأمونيوم والكلورال هيدرات والمستخدمة كسوائل، كان لها تأثير موجب على الصفات المدروسة للهيموليمف فى السلالة المحلية أو المستوردة لدودة القز. تم إجراء تحليل إحصائى تفصيلى وتمت مقارنة ومناقشة النتائج الخاصة بالمعاملات والسلالتين موضع الإختبار.
