## Cadmium Toxicity Alleviates by Seed Priming with Proline or Glycine Betaine in Cowpea (*Vigna unguiculata* (L.) Walp.)

### Omid Sadeghipour

*Department of Agronomy, Yadegar-e-Imam Khomeini (RAH) Shahre Rey Branch, Islamic Azad University, Tehran 18155/144, Iran.*

CADMIUM (Cd) as a non-essential metal is a soil pollutant that inhibits plant growth and development. Proline (Pro) and Glycine betaine (GB) are two important compatible solutes that accumulate in response to abiotic stresses in different plant species. Here, a pot experiment was carried out to assess the role of exogenously applied Pro and GB in improving Cd toxicity tolerance in cowpea plants. Seeds were soaked in 0, 25 and 50mM Pro or GB, and then were sown in plastic pots that were irrigated with 0 or 100µM cadmium chloride. Results showed that Cd stress markedly decreased shoot length, shoot biomass, leaf area, chlorophyll value, stomatal conductance and relative water content (RWC) but increased root and shoot Cd levels, malondialdehyde (MDA) content and antioxidant enzyme activities such as superoxide dismutase (SOD), catalase (CAT) and ascorbate peroxidase (APX). Nevertheless, seed treatment with Pro or GB reduced Cd toxicity and improved growth attributes via reducing Cd uptake and translocation, increasing the chlorophyll value, stomatal conductance, and RWC as well as more enhancing the activities of antioxidant enzymes and lowering the MDA level. Although both Pro and GB were effective, pre-treatment of seeds with Pro improved Cd stress tolerance better than GB. Thus, seed treatment with Pro (especially 50mM) could be used as an effective method for protecting cowpea plants against Cd toxicity.

**Keywords:** Cadmium, Glycine betaine, Proline, Seed treatment, Oxidative stress.

## Introduction

Although the cadmium (Cd) level is very low in the earth's crust, various anthropogenic activities such as mining and smelting, application of sewage sludge, compost, phosphate fertilizer, pesticide, and insecticide have led to an increase in the Cd concentration in agricultural soils. Cd as a non-essential heavy metal element is easily taken up by plants due to its high mobility within the soil-plant system. Cd accumulation in the plant can cause biochemical, molecular, physiological and morphological disorders, such as induction of oxidative stress, impairment the activity of various enzymes, reduction of chlorophyll level, stomata opening, photosynthesis and transpiration, disturbance in uptake, transport and use of minerals, water imbalance, leaf rolling, chlorosis and necrosis, root browning, and finally inhibition of growth and productivity (Nagajyoti et al., 2010; Asgher et al., 2015; Shahid et al., 2016).

One of the most common biochemical responses in higher plants under environmental stress conditions is the accumulation of compatible organic solutes such as amino acid proline (Pro) and quaternary ammonium compound glycine betaine (GB). These compounds are low molecular weight, highly soluble and nontoxic at high cellular concentrations. These osmoprotectants protect plants against the stress through various ways, including osmotic adjustment, scavenging reactive oxygen species (ROS), maintenance of membrane integrity, and stabilization of enzymes and proteins (Ashraf & Foolad, 2007). Heavy

metal stress up-regulates the enzymes involved in Pro and GB biosynthesis which contribute in improving stress tolerance (Hossain et al., 2010). However, in many crop plants, the natural accumulation of Pro or GB is not sufficient to protect them against the adverse effects of various environmental stresses such as Cd. Therefore, the exogenous application of Pro or GB may help to enhance Cd stress tolerance. Rasheed et al. (2014) found that foliar application of Pro and GB caused a noticeable alteration in growth and physiochemical traits of two wheat cultivars under Cd stress. Although both Pro and GB were effective, plants treated with Pro had greater shoot and root biomass, leaf phenolics, lower degradation of chlorophylls, and accumulation of malondialdehyde (MDA) and $H_2O_2$ contents under Cd stress. Islam et al. (2009) also reported that both exogenous Pro and GB enhanced tolerance to Cd stress in cultured tobacco BY-2 cells through protecting cellular components, increasing antioxidant enzyme activities and intracellular contents of Pro and GB. Furthermore, Pro was more effective than GB. Application of Pro and GB through irrigation water alleviated the harmful effects of lead (Pb) stress on olive trees by reducing Pb content and increased the enzymatic and non-enzymatic antioxidant systems. Pro had a better influence on reducing Pb toxicity than GB (Zouari et al., 2018).

Cowpea (*Vigna unguiculata* (L.) Walp.) is an important grain and forage legume in the tropical and subtropical regions. In addition to being rich in proteins, vitamins, minerals, fiber, and micronutrients, cowpea increase soil fertility. However, the growth and productivity of this crop are negatively affected by environmental stresses such as Cd toxicity. Although some studies have shown that exogenously applied Pro and GB alleviate Cd toxicity in some plant species, there is little information to compare the role of these organic compounds in reducing Cd toxicity in cowpea. Therefore, the current experiment aimed to evaluate and compare the role of Pro and GB in enhancing Cd toxicity tolerance in cowpea plants by measuring some biochemical, physiological and growth attributes.

## Materials and Methods

*Growth conditions, plant material, and treatments*

This pot experiment was carried out in the research field of the Department of Agronomy, Yadegar-e-Imam Khomeini (RAH) Shahre Rey Branch, Islamic Azad University (35°35′ N; 51°28′ E and 1000 m altitude), Tehran, Iran, during spring and summer seasons of 2017, in a completely randomized design (CRD) with six treatments and four replicates under ambient air and temperature conditions. The meteorological data of the region for the growing season are presented in Table 1.

The plastic pots (50cm in diameter and height) were filled with 15kg soil containing an equal mixture of peat, decomposed manure, and farm soil. The texture of the soil was loam with pH 7.45, EC 1.90dS m⁻¹, organic carbon 2.82 %, N 0.28%, P, K and Cd 18.33, 425.30 and 0.44mg kg⁻¹ soil, respectively. Cowpea seeds (cv. Kamran) were obtained from Pakan Bazr Corporation, Isfahan, Iran. Seeds without visible defect, insect damage or malformation were surface sterilized using 5 % sodium hypochlorite solution for five min and then rinsed three times with sterile distilled water. After sterilization, as a pre-sowing treatment, seeds were soaked for 8 h in different concentrations (0, 25 and 50mM) of Pro or GB. Then, 15 treated seeds were sown at a depth of three cm in each plastic pot on May 10, 2017. After seeding irrigation of the pots was done regularly using tap water. After thinning at the 2-leafy stage, six uniform seedlings were retained per pot and irrigation was done with 0 or 100μM of chloride cadmium as Cd stress treatments.

**TABLE 1. Monthly meteorological data for the growing season of cowpea (2017).**

| Parameters | Mean Temperature (°C) | Precipitation (mm) | Mean Humidity (%) | Sunshine Duration (h) |
|---|---|---|---|---|
| April | 17.6 | 20.5 | 37.3 | 247.4 |
| May | 24.9 | 10.1 | 25.2 | 302.4 |
| June | 28.7 | 0 | 16.3 | 328.7 |
| July | 31.5 | 0 | 21.0 | 356.8 |
| August | 30.0 | 0 | 16.0 | 358.9 |

*Physiological traits assessment*

At the early flowering stage, some physiological and biochemical traits were estimated. The chlorophyll value of the youngest fully expanded leaves was measured using a chlorophyll meter (Chlorophyll Content Meter, CL-01, Hansatech Instruments Ltd. England). Stomatal conductance was measured on a sunny day between 10:00 and 11:00hrs on the youngest fully expanded leaves using a Portable Leaf Porometer, SC-1, Decagon Devices, USA. To determine the relative water content (RWC); 10 disks (1cm in diameter) from the middle portion of the youngest fully expanded leaves were collected, immediately weighed to record the fresh weight (FW), then, rehydrated in petri dishes containing distilled water for 24h under dim light and room temperature to get the turgid weight (TW) and subsequently the discs were oven-dried at 70°C for 48hrs to record the dry weight (DW). RWC was calculated as: RWC (%)= (FW - DW) / (TW - DW) × 100.

*Biochemical traits assessment*

Lipid peroxidation was estimated in terms of MDA content according to the method of Heath & Packer (1968). Fresh leaf samples (500mg) were homogenized in 10mL of 0.1% (w/v) trichloroacetic acid (TCA), and the homogenate solution was centrifuged at 10000rpm for 10min. Then, 1mL of the supernatant was mixed with 4mL of 0.5% (w/v) thiobarbituric acid containing 20% (w/v) TCA. The mixture was heated at 95°C for 30min, cooled rapidly in an ice bath, and then centrifuged at 10000rpm for 10min. The absorbance of the supernatant was recorded at 532nm. The value for non-specific absorption at 600nm was subtracted. The MDA content was calculated using the extinction coefficient of 155mM$^{-1}$ cm$^{-1}$ and expressed as nmol g$^{-1}$ fresh weight.

For preparing the crude enzyme extract, fresh leaf samples (500mg) were homogenized in 5mL of potassium phosphate buffer (100mM, pH 7.0), containing 1mM EDTA and 1% (w/v) polyvinylpyrrolidone (PVP), with the addition of 2mM ascorbate in the case of ascorbate peroxidase assay. The homogenate was centrifuged at 15000rpm for 20min at 4°C and the supernatant was used for the following enzyme assays. Protein concentration was determined by the method of Bradford (1976) using bovine serum albumin as a standard.

Superoxide dismutase (SOD, EC 1.15.1.1) activity was assayed by the inhibition of photochemical reduction of nitro-blue tetrazolium (NBT) at 560nm following the method of Beauchamp & Fridovich (1971). Catalase (CAT, EC 1.11.1.6) activity was determined by monitoring the decomposition of $H_2O_2$ (extinction coefficient 39.4mM$^{-1}$ cm$^{-1}$) at 240nm using the procedure of Aebi (1984). Ascorbate peroxidase (APX, EC 1.11.1.11) activity was assayed according to Nakano & Asada (1981) by the decrease in absorbance of ascorbate (extinction coefficient 2.8mM$^{-1}$ cm$^{-1}$) at 290 nm.

*Growth traits assessment*

At the early flowering stage, shoot length was recorded. The leaf area of plants was also calculated using a leaf area meter (CI-202, CID Bio-Science, USA). Moreover, the above ground plant parts were oven-dried at 80°C for 48hrs and shoot biomass was calculated.

*Cd content assessment*

The oven-dried samples were grounded into a fine powder. Cd concentrations in the root and shoot were estimated after digesting the samples in $HNO_3$-$HClO_4$ (3:1, v/v) using an atomic absorption spectrophotometer (AA-6800, Shimadzu, Japan).

*Statistical analysis*

All data were analyzed by one-way ANOVA, using MSTAT-C statistical software and the means were compared by the least significant difference (LSD) test at P ≤ 0.05.

## Results

*Cd content*

Cd treatment significantly increased Cd accumulation in the root and shoot of cowpea plants as compared with the control. Cd content was greater in the root than in the shoot. An increase by 32 and 23 folds in Cd content comparing to control plants were found in the root and shoot, respectively, under Cd stress. However, seed treatment with Pro or GB, especially 50mM Pro, significantly reduced the accumulation of Cd in the root and shoot (Table 2).

**TABLE 2. Effects of different concentrations of proline (Pro) and glycine betaine (GB) on root and shoot Cd content, malondialdehyde (MDA) level and antioxidant enzyme activities of cowpea plants under cadmium (Cd) stress.**

| Treatments | Root Cd ($\mu$g g$^{-1}$ D.W.) | Shoot Cd ($\mu$g g$^{-1}$ D.W.) | MDA (nmol g$^{-1}$ F.W.) | SOD (Unit mg$^{-1}$ pro.) | CAT (Unit mg$^{-1}$ pro.) | APX (Unit mg$^{-1}$ pro.) |
|---|---|---|---|---|---|---|
| Control | 1.43 e | 0.63 e | 12.24 d | 16.32 d | 20.21 d | 12.17 e |
| Cd | 45.77 a | 14.38 a | 18.84 a | 19.95 c | 25.26 c | 14.30 d |
| Cd + Pro (25mM) | 18.93 c | 8.98 c | 16.54 b | 31.60 ab | 41.44 b | 21.76 b |
| Cd + Pro (50mM) | 15.51 d | 7.48 d | 15.59 c | 33.98 a | 45.84 a | 22.91 a |
| Cd + GB (25mM) | 23.75 b | 10.47 b | 16.85 b | 29.50 b | 38.78 b | 20.39 c |
| Cd + GB (50mM) | 20.63 c | 9.73 bc | 17.24 b | 30.95 b | 40.02 b | 21.30 bc |
| LSD | 1.85 | 0.88 | 0.92 | 2.80 | 3.31 | 1.02 |

Means within a column followed by the same letter (s) are not significantly different at P ≤ 0.05 level using LSD. Data are mean ± SE (*n*= 4).

*MDA content*

The MDA content as an indicator of membrane lipid peroxidation severely elevated during Cd stress by 54 % as compared to non-stress conditions. Nonetheless, seed soaking in Pro or GB alleviated the adverse effect of Cd on membrane lipid peroxidation and consequently reduced the MDA content. Among the seed treatments, 50 mM Pro was the most effective (Table 2).

*Antioxidant enzyme activities*

Cd stress markedly raised SOD, CAT and APX activities by 22.2, 25 and 17.5%, respectively, compared with the control. On the other hand, seed priming with Pro or GB, especially 50mM Pro, further increased the activities of these antioxidant enzymes under Cd stress (Table 2).

*Chlorophyll value*

Cd stress caused a significant decrease in the chlorophyll value by 42% as compared with the control. Nevertheless, the treatment of seeds with Pro or GB enhanced the chlorophyll value under Cd stress. The highest improvement in the chlorophyll value was achieved at 50mM Pro (Table 3).

*Stomatal conductance*

Upon exposure to Cd stress, the stomatal conductance of cowpea leaves decreased noticeably by 39.3% compared to the control. However, seed treatment with Pro or GB, especially 50 mM Pro, improved the stomatal conductance under Cd stress (Table 3).

*RWC*

Cd toxicity caused a significant reduction in the RWC of cowpea leaves by 34.1% in comparison with the control. Nonetheless, seed priming with Pro or GB elevated the RWC under Cd stress conditions. Among the seed treatments, 50mM Pro was the most effective (Table 3).

*Growth traits*

Cowpea growth attributes including shoot length, shoot biomass and leaf area markedly decreased due to Cd stress by 39.8, 65 and 51.3%, respectively, compared with the control. On the other hand, seed soaking in Pro or GB significantly enhanced the above characteristics under Cd stress conditions. The maximum improvement in terms of the growth traits was recorded at 50mM Pro (Table 3).

**Discussion**

In the current experiment, Cd toxicity markedly reduced the growth attributes of cowpea plants, including shoot length, shoot biomass and leaf area. These results are in conformity with the previous findings on different plant species (Jhanji et al., 2012; Perveen et al., 2016; Sun et al., 2016; Chen et al., 2018). Nonetheless, seed priming with Pro or GB, especially 50mM Pro, improved all measured growth parameters under Cd stress. Similarly, the positive role of exogenously applied Pro and GB on the growth traits of various plants has been reported under Cd (Rasheed et al., 2014), Pb (Zouari et al., 2018) and Ni (Shahbaz et al., 2019) stress conditions.

**TABLE 3. Effects of different concentrations of proline (Pro) and glycine betaine (GB) on some physiological and growth traits of cowpea plants under cadmium (Cd) stress.**

| Treatments | Chlorophyll value (Spad unit) | Stomatal conductance (mmol m$^{-2}$ s$^{-1}$) | RWC (%) | Shoot length (cm) | Shoot biomass (g plant$^{-1}$) | Leaf area (cm$^2$ plant$^{-1}$) |
|---|---|---|---|---|---|---|
| Control | 38.25 a | 13.51 a | 92.48 a | 76.02 a | 110.47 a | 824.54 a |
| Cd | 22.19 d | 8.20 d | 60.75 d | 45.75 d | 38.61 d | 401.39 d |
| Cd + Pro (25mM) | 27.24 bc | 10.00 bc | 71.67 bc | 56.76 bc | 62.62 bc | 574.16 bc |
| Cd + Pro (50mM) | 29.29 b | 10.65 b | 77.91 b | 60.43 b | 71.71 b | 611.11 b |
| Cd + GB (25mM) | 26.00 c | 9.61 c | 68.59 c | 55.68 c | 57.13 c | 530.48 c |
| Cd + GB (50mM) | 26.66 bc | 9.89 bc | 70.84 bc | 56.54 bc | 62.11 bc | 562.39 bc |
| LSD | 3.10 | 0.86 | 7.11 | 4.60 | 14.24 | 79.39 |

Means within a column followed by the same letter (s) are not significantly different at P ≤ 0.05 level using LSD. Data are mean ± SE (*n*= 4).

In the present study, when cowpea plants were exposed to Cd, the accumulation of Cd in the root was much higher than in the shoot. This result is in accordance with the previous reports on different plant species (Gaballah & Rady, 2012; Mostofa et al., 2015; Ahmad et al., 2016). Higher Cd content in the root as compared to the shoot is one of the most important defense mechanisms of plants against Cd toxicity (Ahmad et al., 2016; Rahman et al., 2017), because of Cd accumulated in the root is immobilized by the cell wall and extracellular carbohydrates (Ahmad et al., 2016). Nevertheless, in the current experiment, seed priming with Pro or GB not only reduced Cd accumulation in the root but also markedly decreased its translocation from the root to shoot. Reduction of Cd uptake and translocation in cowpea plants by exogenous application of Pro or GB in this research is in concurrence with the earlier researches (Islam et al., 2009; Zouari et al., 2016). According to these findings, Pro and GB play an important role in reducing Cd toxicity in cowpea plants by reduction of Cd uptake and translocation to the above-ground parts.

MDA, an end product of membrane lipid peroxidation is a proper marker for oxidative stress by heavy metal toxicity. In the current experiment, an elevated level of MDA in cowpea leaves was observed in Cd treated plants, which is conformity with the other findings (Shamsi et al., 2008; Ahmad et al., 2016; Chen et al., 2018). However, in this study, seed priming with Pro or GB significantly reduced the MDA level under Cd toxicity. Similarly, reduction of MDA content by exogenous application of Pro or GB

under Cd stress conditions have been reported by other authors (Islam et al., 2009; Hossain et al., 2010; Rasheed et al., 2014). The positive effect of Pro and GB on preventing the degradation of biological membranes due to oxidative damage is attributed to their potential role in membrane stability, scavenging ROS, and the activation of antioxidant enzymes (Ashraf & Foolad, 2007; Hasanuzzaman et al., 2014).

Although Cd is not a redox-active metal and unable to produce ROS directly via Fenton and Haber-Weiss reactions, indirect ROS production is common in Cd-exposed plants (Shahid et al., 2016). At high concentrations, ROS can react with proteins, lipids, and nucleic acids, causing alteration or loss of structure and function which leads to lipid peroxidation and membrane leakage, enzyme inactivity, and DNA breakage and mutation (Andresen & Kupper, 2013). To scavenging excessive ROS, plants have developed antioxidant defense systems. ROS are efficiently scavenged by enzymatic (SOD; CAT; APX; GR; MDHAR; DHAR; GOPX and GST) and non-enzymatic (ascorbate, glutathione, phenolic compounds, alkaloids, non-protein amino acids and α-tocopherols), antioxidant systems, which protect them against oxidative damage. The enzymes SOD and CAT are involved in the detoxification of $O_2 \cdot^-$ and $H_2O_2$, respectively, thereby preventing the formation of OH• radicals, whereas, APX and GR, as well as ascorbate (AsA) and glutathione (GSH), are important components of the ascorbate-glutathione cycle responsible for the removal of $H_2O_2$ in different cellular compartments (Gill et al., 2013). In the present

work, the activities of antioxidant enzymes such as SOD, CAT and APX, were enhanced in cowpea plants by Cd stress, and these activities were further increased by seed treatment with Pro or GB under Cd stress conditions. These results suggest that the enhanced activities of these enzymes are beneficial for cowpea response to Cd stress and that Pro and GB can stimulate the activity of antioxidant enzymes, which further strengthens the cowpea plants to withstand Cd toxicity. Similarly, several studies have reported Cd-induced activation of antioxidant enzymes, possibly via modulation of gene expression or Cd-induced restriction of enzyme inhibitors (Mostofa et al., 2015; Rady & Hemida, 2015; Rahman et al., 2017). In accordance with the present findings, exogenous application of Pro or GB enhanced antioxidant enzyme activities in mung bean (Hossain et al., 2010), and tobacco (Islam et al., 2009) under Cd stress.

In the current research, it was found that Cd stress significantly reduced the chlorophyll value of cowpea leaves, while seed treatment with Pro or GB improved this physiological trait under Cd toxicity. The reduction in the chlorophyll content under Cd stress is well known (Moussa & El-Gamal, 2010; Gaballah & Rady, 2012; Jhanji et al., 2012). The reduction of chlorophyll value in cadmium-treated plants is attributed to inhibition of its biosynthesis and also lower concentrations of Mg and Fe in the leaves (Gill et al., 2013). The positive role of exogenously Pro or GB on the chlorophyll value might be due to improving its biosynthesis and reducing its degradation under Cd stress conditions. In agreement with the present findings, treatment with Pro or GB enhanced the chlorophyll content of wheat under Cd stress (Rasheed et al., 2014), and also rice under salinity stress (Hasanuzzaman et al., 2014).

In this study, Cd induced a reduction in stomatal conductance of cowpea leaves. On the other hand, pretreatment of cowpea seeds with Pro or GB improved stomatal conductance under Cd stress conditions. In conformity with these findings, there are several reports that Cd strongly induced closure of stomata in different plant species (Shamsi et al., 2008; Sun et al., 2016; Sadeghipour, 2018). Under Cd stress, stomata were closed independently regardless of the water status. Moreover, Cd led to stomatal closure as a result of Cd entry into the guard cells and it reduced the stomata number per unit area

(Ismael et al., 2019). Pro application caused an increase in stomatal conductance by maintaining appropriate cellular turgor (Wani et al., 2019). De Freitas et al. (2019) found that exogenously Pro elevated $K^+$ and $Ca^+$ accumulation which likely acted in membrane stability and water content, thus regulated stomatal conductance of sorghum plants under salinity stress. Rady et al. (2018) also demonstrated that foliar application of GB as an osmoprotectant increased the stomatal conductance of salt-stressed onion plants via maintaining the endogenous available water.

RWC is an important indicator of water status in plants which is related to water uptake from the roots and transpiration rate from the leaves. In the present study, Cd treatment significantly decreased the RWC of cowpea leaves through inhibition of root growth and stomata closure. In accordance with these results, Cd treatment reduced the RWC of wheat (Moussa & El-Gamal, 2010), pea (Gaballah & Rady, 2012) and common bean (Sadeghipour, 2018). Cd via an effect on stomatal conductance, water transport, and cell wall elasticity could disturb the plant water balance (De Maria et al., 2013). Nonetheless, in this study, seed treatment with Pro or GB through increase the root growth, and stomatal conductance improved the water relations in terms of the RWC under Cd toxicity. In agreement with these findings, Hasanuzzaman et al. (2014) reported that exogenous application of Pro or GB to salt-treated rice seedlings enhanced the RWC which was due to the maintenance of water in their tissue.

## Conclusion

Cd stress caused oxidative stress and led to a significant decrease in chlorophyll value, stomatal conductance, RWC and finally growth attributes of cowpea plants. Nonetheless, pre-treatment of seeds with Pro or GB reduced the harmful effects of Cd. Pro was more effective than GB in mitigating the detrimental effects of Cd stress by reducing Cd uptake and translocation, improving chlorophyll value, stomatal conductance, and RWC, as well as enhance antioxidant enzyme activities and preventing membrane lipid peroxidation.
